## 1 Basic Number Theory

### 1.1 Definitions

Divisibility:

$$
a \mid b \Longleftrightarrow \exists k \in \mathbb{Z}[b=a k]
$$

Congruences:

$$
a \equiv b \quad(\bmod n) \Longleftrightarrow n \mid(a-b)
$$

Modulo operator: (Maple irem, mod)

$$
b \bmod n=\min \{a \geq 0: a \equiv b \quad(\bmod n)\}
$$

Division operator: (Maple iquo)

$$
b \operatorname{div} n=\lfloor b / n\rfloor=\frac{b-(b \bmod n)}{n}
$$

## Euclid

Greatest Common Divider: (Maple igcd, igcdex)

$$
g=\operatorname{gcd}(a, b) \Longleftrightarrow g|a, g| b \text { and }\left[g^{\prime}\left|a, g^{\prime}\right| b \Rightarrow g^{\prime} \mid g\right]
$$

Euler's Phi function: (Maple phi)

$$
\phi(n)=\#\{a: 0<a<n \text { and } \operatorname{gcd}(a, n)=1\}
$$

Note. $\phi(p)=p-1$, where $p$ is prime, $\phi(p q)=(p-1)(q-1)$, where $p$ and $q$ are primes, and in general, $\phi(n)=\left(p_{1}-1\right) p_{1}^{e_{1}-1}\left(p_{2}-1\right) p_{2}^{e_{2}-1} \ldots\left(p_{k}-1\right) p_{k}^{e_{k}-1}$, where $n=p_{1}^{e_{1}} p_{2}^{e_{2}} \ldots p_{k}^{e_{k}}$ is a generic product of distinct prime powers.

### 1.2 Efficient operations

For the basic operations of,,$+- \times$, mod , div one may use standard "elementary school" algorithms reducing the work load by the following rules:

$$
a\left\{\begin{array}{l}
+ \\
- \\
x
\end{array}\right\} b \bmod n=\left((a \bmod n)\left\{\begin{array}{c}
+ \\
- \\
x
\end{array}\right\}(b \bmod n)\right) \bmod n
$$

The standard "elementary school" algorithms are precisely described in Knuth (Vol 2). For very large numbers, special purpose divide-and-conquer algorithms may be used for better efficiency of $x$, mod, div. Consult the algorithmics book of Brassard-Bratley for these.

$$
\begin{array}{|r}
\hline 423 \times 211 \\
\\
\hline 2211 \\
\hline 423 \\
+846 \\
\hline
\end{array}
$$

$$
\begin{array}{|ll|}
\hline \frac{193}{\sqrt{2}} & \\
5 \longdiv { 9 6 5 } & 3 \times 5=15 \\
-\frac{5}{46} & \\
\frac{-45}{15} & \\
15 \\
\hline
\end{array}
$$

### 1.2.1 Fast modular exponentiation

The idea behind this algorithm is to maintain in each iteration the value of the expression $x a^{e} \bmod n$ while reducing the exponent $e$ by a factor 2 .

## Algorithm $1.1\left(a^{e} \bmod n\right)$

1: $x \leftarrow 1$,
2: WHILE $e>0$ DO
3: IF $e$ is odd THEN $x \leftarrow a x \bmod n$,
4: $a \leftarrow a^{2} \bmod n, e \leftarrow e \operatorname{div} 2$,
5: ENDWHILE
6: RETURN $x$.
(Maple x\&\& ${ }^{\wedge} \bmod n$ )

### 1.2.2 GCD calculations and multiplicative inverses

Note. $\operatorname{gcd}(a, b)=g \rightarrow \exists_{x, y} \in \mathbb{Z}$ such that $g=a x+b y$. The following recursive definition is based on the property $\operatorname{gcd}(a, b)=\operatorname{gcd}(a, b-a)$.

$$
\operatorname{gcd}(a, b)= \begin{cases}a & \text { if } b=0 \\ \operatorname{gcd}(b, a \bmod b) & \text { otherwise }\end{cases}
$$

The idea behind the following iterative algorithm is to maintain in each iteration the relations $g=a x+b y$ and $g^{\prime}=a x^{\prime}+b y^{\prime}$ while reducing the value of $g$.

At the end of the algorithm, the value of $g$ is $\operatorname{gcd}(a, b)$. The final value of $x$ is such that $a x \equiv g(\bmod b)$ and by symmetry, the final value of $y$ is such that by $\equiv g(\bmod a)$. When $\operatorname{gcd}(a, b)=1$, we find that $x$ is the multiplicative inverse of $a$ modulo $b$ and that $y$ is the multiplicative inverse of $b$ modulo $a$.

## Algorithm 1.2 (Euclide $\operatorname{gcd}(a, b)$ )

1: $g \leftarrow a, g^{\prime} \leftarrow b, x \leftarrow 1, y \leftarrow 0, x^{\prime} \leftarrow 0, y^{\prime} \leftarrow 1$,
2: WHILE $g^{\prime}>0$ DO
$3: k \leftarrow g \operatorname{div} g^{\prime}$,
4: $(\hat{g}, \hat{x}, \hat{y}) \leftarrow(g, x, y)-k\left(g^{\prime}, x^{\prime}, y^{\prime}\right)$,
$5:(g, x, y) \leftarrow\left(g^{\prime}, x^{\prime}, y^{\prime}\right)$,
$6:\left(g^{\prime}, x^{\prime}, y^{\prime}\right) \leftarrow(\hat{g}, \hat{x}, \hat{y})$,

## 7: ENDWHILE

8: RETURN $(g, x, y)$.
(Maple igcd, igcdex, $\left.x^{\wedge}(-1) \bmod n, 1 / x \bmod n\right)$

### 1.3 Solving linear congruentials

A linear congruential is an expression of the form

$$
b \equiv a x \quad(\bmod n)
$$

for known $a, b, n$ and unknown $x$. Clearly, we can solve for $x$ whenever $\operatorname{gcd}(a, n)=1$ since in that case $a^{-1}(\bmod n)$ exists and thus

$$
x \equiv b a^{-1} \quad(\bmod n) .
$$

Similarily, when $\operatorname{gcd}(a, n)=g>1$ the situation can be modified to apply the same strategy. If it is the case that $g \mid b$ as well, we can solve the following system instead, where $a^{\prime}=\frac{a}{g}, b^{\prime}=\frac{b}{g}, n^{\prime}=\frac{n}{g}$ :

$$
a^{\prime} x^{\prime} \equiv b^{\prime} \quad\left(\bmod n^{\prime}\right)
$$

Since $\operatorname{gcd}\left(a^{\prime}, n^{\prime}\right)=1, a^{\prime-1}\left(\bmod n^{\prime}\right)$ exists and we can solve for $x^{\prime}$

$$
x^{\prime} \equiv b^{\prime} a^{\prime-1} \quad\left(\bmod n^{\prime}\right)
$$

Note however, that no solution exists if $g \nmid b$.

Finally, we know that a solution $x$ modulo $n$ must satisfy $x \equiv x^{\prime}\left(\bmod n^{\prime}\right)$. Thus we can write

$$
x=x^{\prime}+k n^{\prime}
$$

and consider all such $x$ with $0 \leq k<g$. All these $g$ posibilties for $x$ will be valid solutions to the original system.

## Summary:

to solve $b \equiv a x(\bmod n)$ :
Let $g=\operatorname{gcd}(a, n)$.
If $g \nmid b$ then there are no solutions otherwise there are $g$ distinct solutions, for $0 \leq k<g$, given by

$$
x=x^{\prime}+k n^{\prime}
$$

where $n^{\prime}=\frac{n}{g}, x^{\prime} \equiv b^{\prime} a^{\prime-1}\left(\bmod n^{\prime}\right), a^{\prime}=\frac{a}{g}, b^{\prime}=\frac{b}{g}$.

### 1.3.1 Chinese Remainder Theorem

Theorem 1.1 (Chinese Remainder (Maple chrem)) Let $m_{1}, m_{2}, \ldots, m_{r}$ be $r$ positive integers such that $\operatorname{gcd}\left(m_{i}, m_{j}\right)=1$ for $1 \leq i<j \leq r$ and let $a_{1}, a_{2}, \ldots, a_{r}$ be integers. The system of $r$ congruences $x \equiv a_{i}\left(\bmod m_{i}\right)$, for $1 \leq i \leq r$ has a unique solution modulo $M=m_{1} m_{2} \ldots m_{r}$ which is given by

$$
x=\sum_{i=1}^{r} a_{i} M_{i} y_{i} \bmod M
$$

where $M_{i}=M / m_{i}$ and $y_{i}=M_{i}^{-1} \bmod m_{i}$, for $1 \leq i \leq r$.

### 1.4 Quadratic Residues

Quadratic residues modulo $n$ are the integers with an integer square root modulo $n$ (Maple quadres):

$$
\begin{gathered}
Q R_{n}=\left\{a: \operatorname{gcd}(a, n)=1, \exists r\left[a \equiv r^{2} \quad(\bmod n)\right]\right\} \\
Q N R_{n}=\left\{a: \operatorname{gcd}(a, n)=1, \forall r\left[a \neq r^{2} \quad(\bmod n)\right]\right\}
\end{gathered}
$$

Example:

$$
\begin{aligned}
Q R_{17} & =\{1,2,4,8,9,13,15,16\} \\
Q N R_{17} & =\{3,5,6,7,10,11,12,14\}
\end{aligned}
$$

since

$$
\begin{gathered}
\left\{1^{2}, 2^{2}, 3^{2}, 4^{2}, 5^{2}, 6^{2}, 7^{2}, 8^{2}, 9^{2}, 10^{2}, 11^{2}, 12^{2}, 13^{2}, 14^{2}, 15^{2}, 16^{2}\right\} \equiv \\
\{1,2,4,8,9,13,15,16\}(\bmod 17)
\end{gathered}
$$

Theorem 1.2 Let $p$ be an odd prime number

$$
\# Q R_{p}=\# Q N R_{p}=(p-1) / 2
$$

### 1.4.1 Legendre and Jacobi Symbols

For an odd prime number $p$, we define the Legendre symbol (Maple legendre) as

$$
\binom{a}{p}=\left\{\begin{aligned}
+1 & \text { if } a \in Q R_{p} \\
-1 & \text { if } a \in Q N R_{p} \\
0 & \text { if } p \mid a
\end{aligned}\right.
$$

For any integer $n=p_{1} p_{2} \ldots p_{k}$, we define the Jacobi symbol (Maple jacobi) (a generalization of the Legendre symbol) as

Adrien-Marie Legendre

$$
\left(\frac{a}{n}\right)=\left(\frac{a}{p_{1}}\right)\left(\frac{a}{p_{2}}\right) \ldots\left(\frac{a}{p_{k}}\right)
$$

## Properties

$$
\begin{gathered}
\left(\frac{1}{n}\right)=+1 \\
\left(\frac{a b}{n}\right)=\left(\frac{a}{n}\right)\left(\frac{b}{n}\right) \\
\left(\frac{a}{n}\right)=\left(\frac{a \bmod n}{n}\right)
\end{gathered}
$$

For $n$ odd

$$
\begin{aligned}
& \left(\frac{-1}{n}\right)=(-1)^{(n-1) / 2} \\
& \left(\frac{2}{n}\right)=(-1)^{\left(n^{2}-1\right) / 8}
\end{aligned}
$$

For $a, n$ odd and such that $\operatorname{gcd}(a, n)=1$

$$
\left(\frac{a}{n}\right)\left(\frac{n}{a}\right)=(-1)^{(n-1)(a-1) / 4}
$$

Algorithm 1.3 ( $\operatorname{Jacobi}(a, n)$ )

1:if $a \leq 1$ then return $a$
else if $a$ is odd then if $a \equiv n \equiv 3(\bmod 4)$
then return -Jacobi $(n \bmod a, a)$
else return $+J a c o b i(n \bmod a, a)$
else if $n \equiv \pm 1(\bmod 8)$
then return $+J \operatorname{Jcobi}(a / 2, n)$
else return - Jacobi $(a / 2, n)$
This algorithm runs in $O\left((\lg n)^{2}\right)$ bit operations.

## Pierre de Fermat

### 1.4.2 Fermat-Euler

Theorem 1.3 (Fermat) Let $p$ be a prime number and a be an integer not a multiple of $p$, then

$$
a^{p-1} \equiv 1 \quad(\bmod p) .
$$

Theorem 1.4 Let $p$ be a prime number and $a$ be an integer, then

$$
a^{(p-1) / 2}=\left(\frac{a}{p}\right) \quad(\bmod p) .
$$

Theorem 1.5 (Euler) Let $n$ be an integer and a another integer such that $\operatorname{gcd}(a, n)=1$, then

$$
a^{\phi(n)} \equiv 1 \quad(\bmod n) .
$$

### 1.4.3 Extracting Square Roots modulo $p$

Theorem 1.6 For prime numbers $p \equiv 3(\bmod 4)$ and $a \in Q R_{p}$, we have that $r=a^{(p+1) / 4} \bmod p$ is a square root of $a$.

## Proof.

$$
\begin{aligned}
\left(a^{(p+1) / 4)}\right)^{2} & \equiv a^{(p-1) / 2} \cdot a(\bmod p) \\
& \equiv a(\bmod p)(\text { Fermat, sec. 1.3) }
\end{aligned}
$$

For prime numbers $p \equiv 1(\bmod 4)$ and $a \in Q R_{p}$, there (only) exists an efficient probabilistic algorithm. We present one found in the algorithmics book of Brassard-Bratley:

## Algorithm 1.4 ( rootLV(a, p, VAR r, VAR success) )

1: $z \leftarrow u n i f o r m(1 \ldots p-1)$
2: IF $a=z^{2} \bmod p$ \{very unlikely\} THEN success $\leftarrow \operatorname{true}, r \leftarrow z$
3: ELSE compute $c$ and $d$ such that $0 \leq c \leq p-1,0 \leq d \leq p-1$, and

$$
c+d \sqrt{a} \equiv(z+\sqrt{a})^{(p-1) / 2} \bmod p
$$

4: IF $d=0$ THEN success $\leftarrow$ false
5: $\quad \operatorname{ELSE}(c=0)$, success $\leftarrow$ true,

Michele Cipolla
$6:$ compute $r$ such that $1 \leq r \leq p-1$ and $d \cdot r \equiv 1 \bmod p$

### 1.4.4 Extracting Square Roots modulo $n$

We want to solve $r^{2} \equiv a(\bmod n)$ for $r$ knowing $p, q$ such that $n=p q$. We first solve modulo $p$ and $q$ and find solutions to

$$
\begin{aligned}
r_{p}^{2} & \equiv a \quad(\bmod p) \\
r_{q}^{2} & \equiv a \quad(\bmod q)
\end{aligned}
$$

We then consider the simultaneous congruences

$$
\begin{aligned}
r \equiv r_{p}(\bmod p) & \Longleftrightarrow p \mid r^{2}-a \\
r \equiv r_{q}(\bmod q) & \Longleftrightarrow q \mid r^{2}-a \\
& \Rightarrow p \cdot q=n \mid r^{2}-a \\
& \Rightarrow r^{2} \equiv a(\bmod n)
\end{aligned}
$$

We can now solve $r$ by the chinese remainder theorem.

Definition 1.7 (SQROOT) The square root modulo $n$ problem can be stated as follows:
given a composite integer $n$ and $a \in Q R_{n}$, find a square root of a mod $n$.
(Maple msqrt)
Theorem 1.8 SQROOT is polynomialy equivalent to FACTORING (see def. section 12.1).

Proof idea: the above construction shows that if we know the factorization of $n$, we can extract square roots modulo each prime factor of $n$ and then recombine using the Chinese Remainder Theorem.

If we can extract square roots modulo $n$, we can split $n$ in two factors $n=u v$ by repeating the following algorithm: Pick a random integer $r$ and extract the square root of $r^{2} \bmod n$, say $r^{\prime}$. If $r^{\prime} \equiv \pm r(\bmod n)$ then try again, else set $u=\operatorname{gcd}\left(r+r^{\prime}, n\right)$ and $v=\operatorname{gcd}\left(r-r^{\prime}, n\right)$. The probability of the second case is at least $1 / 2$.

### 1.5 Prime numbers

If we want a random prime (Maple rand, isprime) of a given size, we use the following theorem to estimate the number of integers we must try before finding a prime. Let $\pi(n)=\#\{a: 0<a \leq n$ and $a$ is prime $\}$.

Theorem $1.9 \lim _{n \rightarrow \infty} \frac{\pi(n) \log n}{n}=1$
To decide whether a number $n$ is prime or not we rely on Miller-Rabin's probabilistic algorithm. This algorithm introduces the notion of "pseudoprimality" base $a$. Miller defined this test as an extension of Fermat's test. If the Extended Riemann Hypothesis is true than it is sufficient to use the test with small values of $a$ to decide whether a number $n$ is prime or composite. However the ERH is not proven and we use the test in a probabilistic fashion as suggested by Rabin.

Michael O. Rabin
Gary L. Miller

## Algorithm 1.5 ( $\operatorname{Pseudo}(a, n)$ )

1: IF $\operatorname{gcd}(a, n) \neq 1$ THEN RETURN "composite",
2: Let $t$ be an odd number and $s$ a positive integer such that $n-1=t 2^{s}$
3: $x \leftarrow a^{t} \bmod n, y \leftarrow n-1$,
4: FOR $i \leftarrow 0 \mathrm{TO} s$
5: IF $x=1$ AND $y=n-1$ THEN RETURN "pseudo",
6: $y \leftarrow x, x \leftarrow x^{2} \bmod n$,

## 7: ENDFOR

8: RETURN "composite".
It is easy to show that if $n$ is prime, then $P \operatorname{seudo}(a, n)$ returns "pseudo" for all $a, 0<a<n$. Rabin showed that if $n$ is composite, then $p \operatorname{seudo}(a, n)$ returns "composite" for at least $3 n / 4$ of the values of $a, 0<a<n$.

## Theorem 1.10

$$
\#\{a: P \operatorname{seudo}(a, n)=\text { "pseudo" }\}\left\{\begin{array}{lll}
=\phi(n) & =n-1 & \text { if } n \text { is prime } \\
\leq \phi(n) / 4 & \leq(n-1) / 4 & \text { if } n \text { is composite. }
\end{array}\right.
$$

To increase the certainty we may repeat the above algorithm as follows.

## Algorithm 1.6 ( Miller-Rabin $\operatorname{prime}(n, k)$ )

1: FOR $i \leftarrow 1$ TO $k$
2: Pick a random element $a, 0<a<n$,
3: IF pseudo $(a, n)=$ "composite" THEN RETURN "composite",
4: ENDFOR
5: RETURN "prime".
We easily deduce that if $n$ is prime, then $\operatorname{prime}(n, k)$ always returns "prime" and that if $n$ is composite, then $\operatorname{prime}(n, k)$ returns "composite" with probability at least $1-(1 / 4)^{k}$. Thus when the algorithm prime returns "composite", it is always a correct verdict. However when it returns "prime" it remains a very small probability that this verdict is wrong.

In August of 2002, Agrawal, Kayal, and Saxena, announced the discovery of a deterministic primality test running in polynomial time. Unfortunately this test is too slow in practice... its running time being $O\left(|n|^{12}\right)$.

To prove that an integer $n$ is prime:
Let $a$ be an integer such that $\operatorname{gcd}(a, n)=1$. $n$ is prime if and only if

$$
(x+a)^{n} \equiv x^{n}+a \quad(\bmod n)
$$

Manindra Agrawal, Neeraj Kayal, and Nitin Saxena

### 1.6 Quadratic Residuosity problem

## Definition 1.11

$$
J_{n}:=\left\{a \in \mathbb{Z}_{n} \left\lvert\,\left(\frac{a}{n}\right)=1\right.\right\}
$$

Theorem 1.12 Let $n$ be a product of two distinct odd primes $p$ and $q$. Then we have that $a \in Q R_{n}$ iff $\left(\frac{a}{p}\right)=\left(\frac{a}{q}\right)=1$.

Definition 1.13 The quadratic residuosity problem $(Q R P)$ is the following: given an odd composite integer $n$ and $a \in J_{n}$, decide whether or not $a$ is a quadratic residue modulo $n$.

Definition 1.14 (pseudosquare) Let $n \geq 3$ be an odd integer. An integer a is said to be a pseudosquare modulo $n$ if $a \in Q N R_{n} \bigcap J_{n}$.

Remark: If n is a prime, then it is easy to decide if $a$ is in $Q R_{n}$, since $a \in Q R_{n}$ iff $a \in J_{n}$, and the Legendre symbol can be efficiently computed by algorithm 1.3.
If $n$ is a product of two distinct odd primes $p$ and $q$, then it follows from theorem 1.12 that if $a \in J_{n}$, then $a \in Q R_{n}$ iff $\left(\frac{a}{p}\right)=1$.

If we can factor $n$, then we can find out if $a \in Q R_{n}$ by computing the Legendre symbol $\left(\frac{a}{p}\right)$.
If the factorization of $n$ is unknown, then there is no efficient algorithm known to decide if $a \in Q R_{n}$.

This leads to the Goldwasser-Micali probabilistic encryption algorithm:
Init: Alice starts by selecting two large distinct prime numbers $p$ and $q$. She then computes $n=p q$ and selects a pseudosquare $y$. $n$ and $y$ will be public, $p$ and $q$ private.

## Algorithm 1.7 ( Goldwasser-Micali probabilistic encryption )

1: Represent message $m$ in binary $\left(m=m_{1} m_{2} \ldots m_{t}\right)$.
2: $\mathbf{F O R} i=1 \mathrm{TO} t \mathrm{DO}$
3: $\quad$ Pick $x \in_{R} \mathbb{Z}_{n}{ }^{*}$
4: $\quad c_{i} \leftarrow y^{m_{i}} x^{2} \bmod n$
5: RETURN $c=c_{1} c_{2} \ldots c_{t}$

Algorithm 1.8 ( Goldwasser-Micali decryption )

1: $\operatorname{FOR} i=1 \mathrm{TO} t \mathrm{DO}$
2: $\quad e_{i} \leftarrow\left(\frac{c_{i}}{p}\right)$ using algo 1.3.
3: $\quad$ IF $e_{i}=1$ THEN $m_{i} \leftarrow 0$ ELSE $m_{i} \leftarrow 1$
4: RETURN $m=m_{1} m_{2} \ldots m_{t}$

## 2 Finite Fields

### 2.1 Prime Fields

Let $p$ be a prime number. The integers $0,1,2, \ldots, p-1$ with operations $+\bmod p$ et $\times \bmod p$ constitute a field $\mathcal{F}_{p}$ of $p$ elements.

- contains an additive neutral element (0)
- each element $e$ has an additive inverse $-e$
- contains an multiplicative neutral element (1)
- each non-zero element $e$ has a multiplicative inverse $e^{-1}$
- associativity

Évariste Galois

- commutativity
- distributivity

Examples $\mathcal{F}_{2}=(\{0,1\}, \oplus, \wedge) . \mathcal{F}_{5}=(\{0,1,2,3,4\},+, \times)$ defined by

| + | 0 | 1 | 2 | 3 | 4 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 1 | 2 | 3 | 4 |
| 1 | 1 | 2 | 3 | 4 | 0 |
| 2 | 2 | 3 | 4 | 0 | 1 |
| 3 | 3 | 4 | 0 | 1 | 2 |
| 4 | 4 | 0 | 1 | 2 | 3 |

| $x$ | 0 | 1 | 2 | 3 | 4 |
| :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 0 | 0 | 0 | 0 | 0 |
| 1 | 0 | 1 | 2 | 3 | 4 |
| 2 | 0 | 2 | 4 | 1 | 3 |
| 3 | 0 | 3 | 1 | 4 | 2 |
| 4 | 0 | 4 | 3 | 2 | 1 |

Other kind of finite fields for numbers $q$ not necessarily prime exist (Maple GF). This is studied in another section. In general we refer to $\mathcal{F}_{q}$ for a finite field, but you may think of the special case $\mathcal{F}_{p}$ if you do not wish to find out about the general field construction.

### 2.1.1 Primitive Elements

In all finite fields $\mathcal{F}_{q}$ (and some groups in general) there exists a primitive element, that is an element $g$ of the field such that $g^{1}, g^{2}, \ldots, g^{q-1}$ enumerate all of the $q-1$ non-zero elements of the field. We use the following theorem to find a primitive element over $\mathcal{F}_{q}$.

Theorem 2.1 Let $l_{1}, l_{2}, \ldots, l_{k}$ be the prime factors of $q-1$ and $m_{i}=(q-1) / l_{i}$ for $1 \leq i \leq k$. An element $g$ is primitive over $\mathcal{F}_{q}$ if and only if

- $g^{q-1}=1$
- $g^{m_{i}} \neq 1$ for $1 \leq i \leq k$

## Algorithm 2.1 ( Primitive(q) )

1: Let $l_{1}, l_{2}, \ldots, l_{k}$ be the prime factors of $q-1$ and $m_{i}=\frac{q-1}{l_{i}}$ for $1 \leq i \leq k$,

## 2: REPEAT

3: pick a random non-zero element $g$ of $\mathcal{F}_{q}$,
4: UNTIL $g^{m_{i}} \neq 1$ for $1 \leq i \leq k$,
5: RETURN $g$.
(Maple primroot, G[PrimitiveElement])
We use the following theorems to estimate the number of field elements we must try in order to find a random primitive element.

Theorem $2.2 \#\left\{g: g\right.$ is a primitive element of $\left.\mathcal{F}_{q}\right\}=\phi(q-1)$.
Theorem 2.3 $\liminf _{n \rightarrow \infty} \frac{\phi(n) \log \log n}{n}=e^{-\gamma} \approx 0.5614594836$
Example: 2 is a primitive element of $\mathcal{F}_{5}$ since $\left\{2,2^{2}, 2^{3}, 2^{4}\right\}=\{2,4,3,1\}$.

Relation to Quadratic residues As an interesting note, if $g$ is a primitive element of the field $\mathcal{F}_{p}$, for a prime $p$, then we have:

$$
\begin{aligned}
Q R_{p} & =\left\{g^{2 i} \bmod p: 0 \leq i<(p-1) / 2\right\} \\
Q N R_{p} & =\left\{g^{2 i+1} \bmod p: 0 \leq i<(p-1) / 2\right\}
\end{aligned}
$$

in other words, the quadratic residues are the even powers of $g$ while the quadratic non-residues are the odd powers of $g$.

Factoring $q-1 \ldots$ The only efficient way we know to finding a primitive element in fields $\mathcal{F}_{q}$ is when the factorization of $q-1$ is known. In general, it may be difficult to factor $q-1$. However, if we are after a large field with a random number of elements, Eric Bach has devised an efficient probabilistic algorithm to generate random integers of a given size with known factorization. Recently, Adam Kalai has invented a somewhat slower algorithm that is much simpler. Suppose we randomly select $r$ with its factorization using Bach's or Kalai's algorithm. We may check whether $r+1$ is a prime or a prime power. In this case a finite field of $r+1$ elements is obtained and a primitive element may be computed.

Eric Bach

Adam Kalai

## Algorithm 2.2 ( Kalai $\operatorname{randfact(n))}$

1: Generate a sequence $n=s_{0} \geq s_{1} \geq s_{2} \geq \ldots \geq s_{\ell}=1$ by picking $s_{i+1} \in_{R}\left\{1,2, \ldots, s_{i}\right\}$, until reaching $s_{\ell}=1$.

2: Let $r$ be the product of the prime $s_{i}$ 's, $1 \leq i \leq \ell$.
3: IF $r \leq n$ THEN with probability $r / n$ RETURN ( $r$, \{prime $s_{i}$ 's\}).

## 4: Otherwise, RESTART.

Theorem 2.4 The probability of producing $r$ at step 2 is $M_{n} / r$, where $M_{n}=$ $\prod_{p \leq n}(1-1 / p)$.

Thus by outputting $r$ with probability $r / n$ in step 3 , each possible value is generated with equal probability $\frac{M_{n}}{r} \frac{r}{n}=\frac{M_{n}}{n}$. The overall probability that some small enough $r$ is produced and chosen in step 3 is $\sum_{1 \leq r \leq n} \frac{M_{n}}{n}=M_{n}$.

Theorem $2.5 \lim _{n \rightarrow \infty} M_{n} \log n=e^{-\gamma} \approx 0.5614594836$

### 2.2 Polynomials over a field

A polynomial over $\mathcal{F}_{p}$ is specified by a finite sequence $\left(a_{n}, a_{n-1}, \ldots, a_{1}, a_{0}\right)$ of elements from $\mathcal{F}_{p}$, with $a_{n} \neq 0$. The number $n$ is the degree of the polynomial. We have operations,,$+- x$ on polynomials analogous to the similar integer operations. Addition and subtraction are performed componentwise using the addition + and subtraction - of the field $\mathcal{F}_{p}$.

Products are computed by adding all the products of coefficients associated to pairs of exponents adding to a specific exponent.

Example:

$$
\begin{aligned}
& \left(x^{4}+x+1\right) \times\left(x^{3}+x^{2}+x\right) \\
& =x^{4} \times\left(x^{3}+x^{2}+x\right)+x \times\left(x^{3}+x^{2}+x\right)+1 \times\left(x^{3}+x^{2}+x\right) \\
& =\left(x^{7}+x^{6}+x^{5}\right)+\left(x^{4}+x^{3}+x^{2}\right)+\left(x^{3}+x^{2}+x\right) \\
& =x^{7}+x^{6}+x^{5}+x^{4}+(1+1) x^{3}+(1+1) x^{2}+x \\
& =x^{7}+x^{6}+x^{5}+x^{4}+x
\end{aligned}
$$

We also have operations $g(x) \bmod h(x)$ (Maple modpol, rem) and $g(x)$ div $h(x)$ (Maple quo) defined as the unique polynomials $r(x)$ and $q(x)$ such that $g(x)=q(x) h(x)+r(x)$ with $\operatorname{deg}(r)<\operatorname{deg}(h)$. They are obtained by formal division of $g(x)$ by $h(x)$ similar to what we do with integers.

Example:

$$
\begin{aligned}
x^{7}+x^{6}+x^{5}+x^{4}+x & =\left(x^{2}\right) \times\left(x^{5}+x^{2}+1\right)+\left(x^{6}+x^{5}+x^{2}+x\right) \\
& =\left(x^{2}+x\right) \times\left(x^{5}+x^{2}+1\right)+\left(x^{5}+x^{3}+x^{2}\right) \\
& =\left(x^{2}+x+1\right) \times\left(x^{5}+x^{2}+1\right)+\left(x^{3}+1\right)
\end{aligned}
$$

thus

$$
\begin{array}{r}
\left(x^{7}+x^{6}+x^{5}+x^{4}+x\right) \bmod \left(x^{5}+x^{2}+1\right)=x^{3}+1 \\
\left(x^{7}+x^{6}+x^{5}+x^{4}+x\right) \operatorname{div}\left(x^{5}+x^{2}+1\right)=x^{2}+x+1
\end{array}
$$

Exponentiations for integer powers modulo a polynomial are computed using an analogue of algorithm 1.1 (Maple powermod) and $\operatorname{gcd}$ (Maple gcd) of polynomials or multiplicative inverses (Maple gcdex, modpol $(1 / x, q(x), x, p)$ ) are computed using an analogue of algorithm 1.2.

### 2.2.1 Irreducible Polynomials

A polynomial $g(x)$ is irreducible (Maple irreduc) if it is not the product of two polynomials $h(x), k(x)$ of lower degrees. We use the following theorem to find irreducible polynomials.

Theorem 2.6 Let $l_{1}, l_{2}, \ldots, l_{k}$ be the prime factors of $n$ and $m_{i}=n / l_{i}$ for $1 \leq i \leq k$. A polynomial $g(x)$ of degree $n$ is irreducible over $\mathcal{F}_{p}$ iff

- $g(x) \mid x^{p^{n}}-x$
- $\operatorname{gcd}\left(g(x), x^{p^{p_{i}}}-x\right)=1$ for $1 \leq i \leq k$

| $\mathcal{F}_{2}$ |  |
| ---: | ---: |
| $x+1$ | $x^{9}+x^{4}+1$ |
| $x^{2}+x+1$ | $x^{10}+x^{3}+1$ |
| $x^{3}+x+1$ | $x^{11}+x^{2}+1$ |
| $x^{4}+x+1$ | $x^{12}+x^{6}+x^{4}+x+1$ |
| $x^{5}+x^{2}+1$ | $x^{13}+x^{4}+x^{3}+x+1$ |
| $x^{6}+x+1$ | $x^{14}+x^{10}+x^{6}+x+1$ |
| $x^{7}+x^{3}+1$ | $x^{15}+x+1$ |
| $x^{8}+x^{4}+x^{3}+x^{2}+1$ | $x^{16}+x^{12}+x^{3}+x+1$ |

Figure 1: Irreducible polynomials over $\mathcal{F}_{2}$.

$$
\begin{array}{|r||r||r|}
\mathcal{F}_{3} & \mathcal{F}_{5} & \mathcal{F}_{7} \\
\hline x^{2}+1 & x+1 & x+1 \\
x^{2}+x+2 & x^{2}+x+2 & x^{2}+x+3 \\
x^{4}+2 x+1 & x^{3}+3 x+2 & x^{3}+3 x+2
\end{array}\left|\begin{array}{l|l}
x^{4}+x+2 & x^{4}+x^{2}+x+2
\end{array}\right|
$$

Figure 2: Irreducible polynomials over $\mathcal{F}_{3}, \mathcal{F}_{5}, \mathcal{F}_{7}$.

## Algorithm 2.3 ( Rabin $\operatorname{Irr}(p, n)$ )

1: let $l_{1}, l_{2}, \ldots, l_{k}$ be the prime factors of $n$ and $m_{i}=n / l_{i}$ for $1 \leq i \leq k$,

## 2: REPEAT

3: pick a random polynomial $h(x)$ of degree $n-1$ over $\mathcal{F}_{p}$, and set $g(x) \leftarrow x^{n}+h(x)$,

4: UNTIL $x^{p^{n}} \bmod g(x)=x$ and
$\operatorname{gcd}\left(g(x), x^{p^{m_{i}}} \bmod g(x)-x\right)=1$ for $1 \leq i \leq k$,

## 5: RETURN $g$.

We use the following theorem to estimate the number of polynomials we have to try on average before finding one that is irreducible.

Theorem 2.7 Let $m(n)$ be the number of irreducible polynomials $g(x)$ of degree $n$ of the form $g(x)=x^{n}+h(x)$ where $h(x)$ is of degree $n-1$. We have

$$
\frac{p^{n}}{2 n} \leq \frac{p^{n}-p^{n / 2} \log n}{n} \leq m(n) \leq \frac{p^{n}}{n} .
$$

### 2.3 General Fields

Let $p$ be a prime number and $n$ a positive integer. We construct a field with $p^{n}$ elements (Maple GF) from the basis field $\mathcal{F}_{p}$ with $p$ elements.

- The elements of $\mathcal{F}_{p^{n}}$ are of the form $a_{1} a_{2} \ldots a_{n}$ where $a_{i}$ is an element of $\mathcal{F}_{p}$.
- The sum of two elements of $\mathcal{F}_{p^{n}}$ is defined by

$$
a_{1} a_{2} \ldots a_{n}+b_{1} b_{2} \ldots b_{n}=c_{1} c_{2} \ldots c_{n}
$$

such that $c_{i}=a_{i}+b_{i}$ for $1 \leq i \leq n$.

- The product of two elements of $\mathcal{F}_{p^{n}}$ is defined by

$$
a_{1} a_{2} \ldots a_{n} \times b_{1} b_{2} \ldots b_{n}=c_{1} c_{2} \ldots c_{n}
$$

such that

$$
\begin{gathered}
\left(c_{1} x^{n-1}+c_{2} x^{n-2}+\ldots+c_{n}\right)= \\
\left(a_{1} x^{n-1}+a_{2} x^{n-2}+\ldots+a_{n}\right) \times\left(b_{1} x^{n-1}+b_{2} x^{n-2}+\ldots+b_{n}\right) \bmod r(x)
\end{gathered}
$$

where $r(x)$ is an irreducible polynomial of degree $n$ over $\mathcal{F}_{p}$.

Examples computations over $\mathcal{F}_{2^{5}}$
$10011+01110=(1+0)(0+1)(0+1)(1+1)(1+0)=11101$

| + | 000 | 001 | 010 | 011 | 100 | 101 | 110 | 111 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 000 | 000 | 001 | 010 | 011 | 100 | 101 | 110 | 111 |
| 001 | 001 | 000 | 011 | 010 | 101 | 100 | 111 | 110 |
| 010 | 010 | 011 | 000 | 001 | 110 | 111 | 100 | 101 |
| 011 | 011 | 010 | 001 | 000 | 111 | 110 | 101 | 100 |
| 100 | 100 | 101 | 110 | 111 | 000 | 001 | 010 | 011 |
| 101 | 101 | 100 | 111 | 110 | 001 | 000 | 011 | 010 |
| 110 | 110 | 111 | 100 | 101 | 010 | 011 | 000 | 001 |
| 111 | 111 | 110 | 101 | 100 | 011 | 010 | 001 | 000 |

$10011 \times 01110=01001$ since $\left(x^{4}+x+1\right) \times\left(x^{3}+x^{2}+x\right) \bmod \left(x^{5}+x^{2}+1\right)=$ $x^{3}+1$.

| $\times$ | 000 | 001 | 010 | 011 | 100 | 101 | 110 | 111 |

### 1.4.5 ${ }^{* * *}$ Extracting Square Roots modulo $p^{c}$

If we have a solution $r$ to $r^{2} \equiv a(\bmod p)$, how do we find a solution $s$ to $s^{2} \equiv a\left(\bmod p^{e}\right)$ for $e>1$ ?

The chinese remainder theorem does not apply here. We have to figure things out in a different way.

First, consider the case $e=2$. Since $r^{2} \equiv a(\bmod p)$, there exists an integer $m=\left(r^{2}-a\right) / p$ such that $r^{2}-a=m p$. Suppose the solution $\bmod p^{2}$ is of the form $s=r+k p$ for some integer $k$. Let's expand $s^{2}$ :

$$
s^{2}=(r+k p)^{2}=r^{2}+2 r k p+(k p)^{2}=m p+a+2 r k p+(k p)^{2}
$$

and therefore

$$
s^{2} \equiv a+(m+2 r k) * p \quad\left(\bmod p^{2}\right) .
$$

We find a solution $s$ by making $m+2 r k$ a multiple of $p$ so that

$$
(m+2 r k) * p \equiv 0 \quad\left(\bmod p^{2}\right) .
$$

The following value of $k$ will acheive our goal

$$
k \equiv-m *(2 r)^{-1} \quad(\bmod p)
$$

and thus remembering $s=r+k p$ we get

$$
s=r-\left(m *(2 r)^{-1} \bmod p\right) * p
$$

and finally remembering $m=\left(r^{2}-a\right) / p$ we obtain a solution

$$
s=r+\left(a-r^{2}\right) *\left((2 r)^{-1} \bmod p\right) .
$$

Second, notice that the same exact reasoning allows to go from the case $p^{e}$ to the case $p^{2 e}$, meaning that any solution $r$ to $r^{2} \equiv a\left(\bmod p^{e}\right)$, can be transformed to a solution $s=r+k p^{e}$ of $s^{2} \equiv a\left(\bmod p^{2 e}\right)$.

Using this argument $i$ times allows to start from a solution $r$ to $r^{2} \equiv a$ $(\bmod p)$, and find a solution $s$ to $s^{2} \equiv a\left(\bmod p^{2^{2}}\right)$.

Finally, to solve the general problem where $e$ is not necessarily a power of 2 , let $i$ be the smallest integer such that $2^{i} \geq e$. From a solution $r$ to $r^{2} \equiv a(\bmod p)$, find a solution to $s^{2} \equiv a\left(\bmod p^{2^{i}}\right)$ and since $p^{e} \mid p^{2^{i}}$ this same solution $s$ will also work $\bmod p^{e}$.

### 2.4 Application of finite fields: Secret Sharing

A polynomial over $\mathcal{F}_{q}$ is specified by a finite sequence $\left(a_{n}, a_{n-1}, \ldots, a_{1}, a_{0}\right)$ of elements from $\mathcal{F}_{q}$, with $a_{n} \neq 0$. The number $n$ is the degree of the polynomial.

Theorem 2.8 (Lagrange's Interpolation) Let $x_{0}, x_{1}, \ldots, x_{d}$ be distinct elements of a field $\mathcal{F}_{q}$ and $y_{0}, y_{1}, \ldots, y_{d}$ be any elements of $\mathcal{F}_{q}$. There exists a unique polynomial $p(x)$ over $\mathcal{F}_{q}$ with degree $\leq d$ such that $p\left(x_{i}\right)=y_{i}$ for $1 \leq i \leq n$.

Algorithm 2.4 ( $\operatorname{Interpolation}\left(x_{0}, x_{1}, \ldots, x_{d}, y_{0}, y_{1}, \ldots, y_{d}\right)$ )

$$
\text { 1: return }\left(\begin{array}{cccc}
1 & x_{0} & \ldots & x_{0}^{d} \\
1 & x_{1} & \ldots & x_{1}^{d} \\
\vdots & \vdots & \ddots & \vdots \\
1 & x_{d} & \cdots & x_{d}^{d}
\end{array}\right)^{-1}\left(\begin{array}{c}
y_{0} \\
y_{1} \\
\vdots \\
y_{d}
\end{array}\right)
$$

Of course the matrix inversion is to be performed over $\mathcal{F}_{q}$, which means all additions, subtractions and multiplications are calculated within the field, and divisions are performed by multiplying with the multiplicative inverse in the field.

Suppose Alice wants to distribute a secret $S$ among $n$ people $P_{1}, P_{2}, \ldots, P_{n}$ in such a way that any $k$ of them can recover the secret from their joint information, while it remains perfectly secret when any $k-1$ or less of them get together. This is what we call a $[n, k]$-secret sharing scheme.

```
Algorithm 2.5 ( \(\operatorname{SSSS}(S)\) )
1: \(a_{0} \leftarrow S\),
2: \(\mathrm{FOR} i:=1 \mathrm{TO} k-1 \mathrm{DO} a_{i} \leftarrow\) uniform \((0 . . p-1)\)
3: FOR \(j:=1 \mathbf{T O} n \mathbf{D O} s_{i} \leftarrow a_{k-1} j^{k-1}+\ldots+a_{1} j+a_{0} \bmod p\)
4: RETURN \(s_{1}, s_{2}, \ldots, s_{n}\).
```

Let's be a bit more formal. Let $S$ be Alice's secret from the finite set $\{0,1,2, \ldots, M\}$ and let $p$ be a prime number greater than $M$ and $n$, the number of share holders. Shamir's construction of a $[n, k]$-secret sharing scheme is as follows.

Share $s_{j}$ is given to $P_{j}$ secretly by Alice. In order to find $S, k$ or more people may construct the matrix from Lagrange's theorem from the distinct values $x_{j}=j$ and find the unique ( $a_{0}, a_{1}, \ldots, a_{k-1}$ ) corresponding to their values $y_{j}=s_{j}$.

Theorem 2.9 For $0 \leq m \leq n$, distinct $j_{1}, j_{2}, \ldots, j_{m}$ and any $s_{j_{1}}, s_{j_{2}}, \ldots, s_{j_{m}}$

$$
S \mid\left[j_{1}, s_{j_{1}}\right],\left[j_{2}, s_{j_{2}}\right], \ldots,\left[j_{m}, s_{j_{m}}\right]= \begin{cases}C & \text { if } m \geq k \\ U & \text { if } m<k\end{cases}
$$

where $C$ is the constant random variable with $\operatorname{Pr}[C=c]=1$ for one single constant $c$ (meaning that the secret is fully determined), and $U$ is the uniform distribution (meaning that the secret is completely undetermined).

Algorithm $2.6\left(\operatorname{Solve}\left(x_{1}, x_{2}, \ldots, x_{m}, s_{1}, s_{2}, \ldots, s_{m}\right)\right)$

$$
\left(\begin{array}{ccccccc}
1 & x_{1} & \ldots & x_{1}^{k+d} & -s_{1} & \ldots & -s_{1} x_{1}^{k-1} \\
1 & x_{2} & \ldots & x_{2}^{k+d} & -s_{2} & \ldots & -s_{2} x_{2}^{k-1} \\
\vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\
\vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\
1 & x_{i} & \ldots & x_{i}^{k+d} & -s_{i} & \ldots & -s_{i} x_{i}^{k-1} \\
\vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\
\vdots & \vdots & \ddots & \vdots & \vdots & \ddots & \vdots \\
1 & x_{m} & \cdots & x_{m}^{k+d} & -s_{m} & \cdots & -s_{m} x_{m}^{k}
\end{array}\right)\left(\begin{array}{c}
n_{0} \\
n_{1} \\
\vdots \\
\vdots \\
n_{k+d} \\
w_{0} \\
w_{1} \\
\vdots \\
w_{k-1}
\end{array}\right)=\left(\begin{array}{c}
s_{1} x_{1}^{k} \\
s_{2} x_{2}^{k} \\
\vdots \\
\vdots \\
s_{i} x_{i}^{k} \\
\vdots \\
\vdots \\
s_{m} x_{m}^{k}
\end{array}\right)
$$
