# The Data Encryption Standard 

### 3.1 Introduction

On May 15, 1973, the National Bureau of Standards published a solicitation for cryptosystems in the Federal Register. This lead ultimately to the development of the Data Encryption Standard, or DES, which has become the most widely used cryptosystem in the world. DES was developed at IBM, as a modification of an earlier system known as LUCIFER. DES was first published in the Federal Register of March 17, 1975. After a considerable amount of public discussion, DES was adopted as a standard for "unclassified" applications on January 15, 1977. DES has been reviewed by the National Bureau of Standards (approximately) every five years since its adoption. Its most recent renewal was in January 1994, when it was renewed until 1998. It is anticipated that it will not remain a standard past 1998.

### 3.2 Description of DES

A complete description of DES is given in the Federal Information Processing Standards Publication 46, dated January 15, 1977. DES encrypts a plaintext bitstring $x$ of length 64 using a key $K$ which is a bitstring of length 56 , obtaining a ciphertext bitstring which is again a bitstring of length 64 . We first give a "high-level" description of the system.

The algorithm proceeds in three stages:

1. Given a plaintext $x$, a bitstring $x_{0}$ is constructed by permuting the bits of $x$ according to a (fixed) initial permutation IP. We write $x_{0}=\operatorname{IP}(x)=L_{0} R_{0}$, where $L_{0}$ comprises the first 32 bits of $x_{0}$ and $R_{0}$ the last 32 bits.
2. 16 iterations of a certain function are then computed. We compute $L_{i} R_{i}$,

## FIGURE 3.1

One round of DES encryption
$1 \leq i \leq 16$, according to the following rule:

$$
\begin{aligned}
& L_{i}=R_{i-1} \\
& R_{i}=L_{i-1} \oplus f\left(R_{i-1}, K_{i}\right)
\end{aligned}
$$

where $\oplus$ denotes the exclusive-or of two bitstrings. $f$ is a function that we will describe later, and $K_{1}, K_{2}, \ldots, K_{16}$ are each bitstrings of length 48 computed as a function of the key $K$. (Actually, each $K_{i}$ is a permuted selection of bits from $K$.) $K_{1}, K_{2}, \ldots, K_{16}$ comprises the key schedule. One round of encryption is depicted in Figure 3.1
3. Apply the inverse permutation $\mathrm{IP}^{-1}$ to the bitstring $R_{16} L_{16}$, obtaining the ciphertext $y$. That is, $y=\operatorname{IP}^{-1}\left(R_{16} L_{16}\right)$. Note the inverted order of $L_{16}$ and $R_{16}$.

The function $f$ takes as input a first argument $A$, which is a bitstring of length 32, and a second argument $J$ that is a bitstring of length 48, and produces as output a bitstring of length 32 . The following steps are executed.

1. The first argument $A$ is "expanded" to a bitstring of length 48 according to a fixed expansion function $\mathrm{E} . \mathrm{E}(A)$ consists of the 32 bits from $A$, permuted in a certain way, with 16 of the bits appearing twice.

FIGURE 3.2
The DES $f$ function
2. Compute $\mathrm{E}(A) \oplus J$ and write the result as the concatenation of eight 6 -bit strings $B=B_{1} B_{2} B_{3} B_{4} B_{5} B_{6} B_{7} B_{8}$.
3. The next step uses eight $S$-boxes $S_{1}, \ldots, S_{8}$. Each $S_{i}$ is a fixed $4 \times 16$ array whose entries come from the integers $0-15$. Given a bitstring of length six, say $B_{j}=b_{1} b_{2} b_{3} b_{4} b_{5} b_{6}$, we compute $S_{j}\left(B_{j}\right)$ as follows. The two bits $b_{1} b_{6}$ determine the binary representation of a row $r$ of $S_{j}(0 \leq r \leq 3)$, and the four bits $b_{2} b_{3} b_{4} b_{5}$ determine the binary representation of a column $c$ of $S_{j}(0 \leq c \leq 15)$. Then $S_{j}\left(B_{j}\right)$ is defined to be the entry $S_{j}(r, c)$, written in binary as a bitstring of length four. (Hence, each $S_{j}$ can be thought of as a function that accepts as input a bitstring of length two and one of length four, and produces as output a bitstring of length four.) In this fashion, we compute $C_{j}=S_{j}\left(B_{j}\right), 1 \leq j \leq 8$.
4. The bitstring $C=C_{1} C_{2} C_{3} C_{4} C_{5} C_{6} C_{7} C_{8}$ of length 32 is permuted according to a fixed permutation P . The resulting bitstring $\mathrm{P}(C)$ is defined to be $f(A, J)$.

The $f$ function is depicted in Figure 3.2. Basically, it consists of a substitution (using an S-box) followed by the (fixed) permutation P. The 16 iterations of $f$ comprise a product cryptosystem, as described in Section 2.5.

In the remainder of this section, we present the specific functions used in DES.

The initial permutation IP is as follows:

| IP |  |  |  |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 58 | 50 | 42 | 34 | 26 | 18 | 10 | 2 |
| 60 | 52 | 44 | 36 | 28 | 20 | 12 | 4 |
| 62 | 54 | 46 | 38 | 30 | 22 | 14 | 6 |
| 64 | 56 | 48 | 40 | 32 | 24 | 16 | 8 |
| 57 | 49 | 41 | 33 | 25 | 17 | 9 | 1 |
| 59 | 51 | 43 | 35 | 27 | 19 | 11 | 3 |
| 61 | 53 | 45 | 37 | 29 | 21 | 13 | 5 |
| 63 | 55 | 47 | 39 | 31 | 23 | 15 | 7 |

This means that the 58th bit of $x$ is the first bit of $\operatorname{IP}(x)$; the 50th bit of $x$ is the second bit of $\operatorname{IP}(x)$, etc.

The inverse permutation $\mathrm{IP}^{-1}$ is:

| $\mathrm{IP}^{-1}$ |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 40 | 8 | 48 | 16 | 56 | 24 | 64 | 32 |
| 39 | 7 | 47 | 15 | 55 | 23 | 63 | 31 |
| 38 | 6 | 46 | 14 | 54 | 22 | 62 | 30 |
| 37 | 5 | 45 | 13 | 53 | 21 | 61 | 29 |
| 36 | 4 | 44 | 12 | 52 | 20 | 60 | 28 |
| 35 | 3 | 43 | 11 | 51 | 19 | 59 | 27 |
| 34 | 2 | 42 | 10 | 50 | 18 | 58 | 26 |
| 33 | 1 | 41 | 9 | 49 | 17 | 57 | 25 |

The expansion function E is specified by the following table:

| E bit-selection table |  |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| 32 | 1 | 2 | 3 | 4 | 5 |
| 4 | 5 | 6 | 7 | 8 | 9 |
| 8 | 9 | 10 | 11 | 12 | 13 |
| 12 | 13 | 14 | 15 | 16 | 17 |
| 16 | 17 | 18 | 19 | 20 | 21 |
| 20 | 21 | 22 | 23 | 24 | 25 |
| 24 | 25 | 26 | 27 | 28 | 29 |
| 28 | 29 | 30 | 31 | 32 | 1 |

The eight S-boxes and the permutation $P$ are now presented:

| $S_{1}$ |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |

| 16 | 7 | 20 | 21 |
| 29 | 12 | 28 | 17 |
| 1 | 15 | 23 | 26 |
| 5 | 18 | 31 | 10 |
| 2 | 8 | 24 | 14 |
| 32 | 27 | 3 | 9 |
| 19 | 13 | 30 | 6 |
| 22 | 11 | 4 | 25 |

Finally, we need to describe the computation of the key schedule from the key $K$. Actually, $K$ is a bitstring of length 64 , of which 56 bits comprise the key and 8 bits are parity-check bits (for error-detection). The bits in positions $8,16, \ldots, 64$ are defined so that each byte contains an odd number of 1 's. Hence, a single error can be detected within each group of 8 bits. The parity-check bits are ignored in the computation of the key schedule.

1. Given a 64 -bit key $K$, discard the parity-check bits and permute the remaining bits of $K$ according to a (fixed) permutation PC-1. We will write $\mathrm{PC}-1(K)=C_{0} D_{0}$, where $C_{0}$ comprises the first 28 bits of PC-1 $(K)$ and $D_{0}$ the last 28 bits.
2. For $i$ ranging from 1 to 16 , compute

$$
\begin{aligned}
C_{i} & =L S_{i}\left(C_{i-1}\right) \\
D_{i} & =L S_{i}\left(D_{i-1}\right)
\end{aligned}
$$

and $K_{i}=\mathrm{PC}-2\left(C_{i} D_{i}\right) . L S_{i}$ represents a cyclic shift (to the left) of either one or two positions, depending on the value of $i$ : shift one position if $i=1,2,9$ or 16 , and shift two positions otherwise. PC-2 is another fixed permutation.

The key schedule computation is depicted in Figure 3.3.
The permutations PC-1 and PC-2 used in the key schedule computation are as follows:

| PC- 1 |  |  |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: |
| 57 | 49 | 41 | 33 | 25 | 17 | 9 |
| 1 | 58 | 50 | 42 | 34 | 26 | 18 |
| 10 | 2 | 59 | 51 | 43 | 35 | 27 |
| 19 | 11 | 3 | 60 | 52 | 44 | 36 |
| 63 | 55 | 47 | 39 | 31 | 23 | 15 |
| 7 | 62 | 54 | 46 | 38 | 30 | 22 |
| 14 | 6 | 61 | 53 | 45 | 37 | 29 |
| 21 | 13 | 5 | 28 | 20 | 12 | 4 |

FIGURE 3.3
Computation of DES key schedule

| $\overline{\text { PC-2 }}$ |  |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: |
| 14 | 17 | 11 | 24 | 1 | 5 |
| 3 | 28 | 15 | 6 | 21 | 10 |
| 23 | 19 | 12 | 4 | 26 | 8 |
| 16 | 7 | 27 | 20 | 13 | 2 |
| 41 | 52 | 31 | 37 | 47 | 55 |
| 30 | 40 | 51 | 45 | 33 | 48 |
| 44 | 49 | 39 | 56 | 34 | 53 |
| 46 | 42 | 50 | 36 | 29 | 32 |

We now display the resulting key schedule. As mentioned above, each round uses a 48-bit key comprised of 48 of the bits in $K$. The entries in the tables below refer to the bits in $K$ that are used in the various rounds.

| Round 1 |  |  |  |  |  |  |  |  |  |  |  |
| ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: | ---: |

| 30 | 5 | 47 | 62 | 45 | 12 | 55 | 38 | 13 | 61 | 31 | 37 |  |  |  |  |
| 6 | 29 | 46 | 4 | 23 | 28 | 53 | 22 | 21 | 7 | 63 | 39 |  |  |  |  |

Decryption is done using the same algorithm as encryption, starting with $y$ as the input, but using the key schedule $K_{16}, \ldots, K_{1}$ in reverse order. The output will be the plaintext $x$.

### 3.2.1 An Example of DES Encryption

Here is an example of encryption using the DES. Suppose we encrypt the (hexadecimal) plaintext

0123456789ABCDEF
using the (hexadecimal) key
133457799 BBCDFF1.
The key, in binary, without parity-check bits, is

## 00010010011010010101101111001001101101111011011111111000.

Applying IP, we obtain $L_{0}$ and $R_{0}$ (in binary):

$$
\begin{aligned}
& L_{0}=11001100000000001100110011111111 \\
& L_{1}=R_{0}=1111000010101010111100010101010 \\
& \hline
\end{aligned}
$$

The 16 rounds of encryption are then performed, as indicated.

| $E\left(R_{0}\right)$ | $=011110100001010101010101011110100001010101010101$ |

### 3.3 The DES Controversy

When DES was proposed as a standard, there was considerable criticism. One objection to DES concerned the S-boxes. All computations in DES, with the exception of the $S$-boxes, are linear, e.g., computing the exclusive-or of two outputs is the same as forming the exclusive-or of two inputs and then computing the output. The S-boxes, being the non-linear component of the cryptosystem, are vital to its security (We saw in Chapter 1 how linear cryptosystems, such as the Hill Cipher, could easily be cryptanalyzed by a known plaintext attack.) However, the design criteria of the S-boxes are not completely known. Several people have suggested that the $S$-boxes might contain hidden "trapdoors" which would allow the National Security Agency to decrypt messages while maintaining that DES is "secure." It is, of course, impossible to disprove such an assertion, but no evidence has come to light that indicates that trap-doors in DES do in fact exist.

In 1976, the National Security Agency (NSA) asserted that the following properties of the $S$-boxes are design criteria:

P0 Each row of each $S$-box is a permutation of the integers $0, \ldots, 15$.
P1 No S-box is a linear or affine function of its inputs.
P2 Changing one input bit to an S-box causes at least two output bits to change.
P3 For any S-box and any input $x, S(x)$ and $S(x \oplus 001100)$ differ in at least two bits (here $x$ is a bitstring of length 6).

Two other properties of the S-boxes were designated as "caused by design criteria" by NSA.

P4 For any S-box, for any input $x$, and for $e, f \in\{0,1\}, S(x) \neq S(x \oplus 11 e f 00)$.
P5 For any S-box, if one input bit is fixed, and we look at the value of one fixed output bit, the number of inputs for which this output bit equals 0 will be "close to" the number of inputs for which the output bit equals 1. (Note that if we fix the value of either the first or sixth input bit, then 16 inputs will cause a particular output bit to equal 0 and 16 inputs will cause the output to equal 1. For the second through fifth input bits, this will not be true, but the resulting distribution will be "close to" uniform. More precisely, for any S-box, if the value of any input bit is fixed, then the number of inputs for which any fixed output bit has the value 0 (or 1 ) is always between 13 and 19.)

It is not publicly known if further design criteria were used in the construction of the S-boxes.

The most pertinent criticism of DES is that the size of the keyspace, $2^{56}$, is too small to be really secure. Various special-purpose machines have been proposed for a known plaintext attack, which would essentially perform an exhaustive search for the key. That is given a 64-bit plaintext $x$ and corresponding ciphertext $y$, every
possible key would be tested until a key $K$ such that $e_{K}(x)=y$ is found (and note that there may be more than one such key $K$ ).

As early as 1977, Diffie and Hellman suggested that one could build a VLSI chip which could test $10^{6}$ keys per second. A machine with $10^{6}$ keys could search the entire key space in about a day. They estimated that such a machine could be built for about $\$ 20,000,000$.

At the CRYPTO '93 Rump Session, Michael Wiener gave a very detailed design of a key search machine. The machine is based on a key search chip which is pipelined, so that 16 encryptions take place simultaneously. This chip can test $5 \times 10^{7}$ keys per second, and can be built using current technology for $\$ 10.50$ per chip. A frame consisting of 5760 chips can be built for $\$ 100,000$. This would allow a DES key to be found in about 1.5 days on average. A machine using 10 frames would cost $\$ 1,000,000$, but would reduce the average search time to about 3.5 hours.

### 3.4 DES in Practice

Even though the description of DES is quite lengthy, it can be implemented very efficiently, either in hardware or in software. The only arithmetic operations to be performed are exclusive-ors of bitstrings. The expansion function E , the S -boxes, the permutations IP and P , and the computation of $K_{1}, K_{2}, \ldots, K_{16}$ can all be done in constant time by table look-up (in software) or by hard-wiring them into a circuit.

Current hardware implementations can attain extremely fast encryption rates. Digital Equipment Corporation announced at CRYPTO ' 92 that they have fabricated a chip with 50 K transistors that can encrypt at the rate of $1 \mathrm{Gbit} /$ second using a clock rate of 250 MHz ! The cost of this chip is about $\$ 300$. As of 1991 , there were 45 hardware and firmware implementations of DES that had been validated by the National Bureau of Standards.

One very important application of DES is in banking transactions, using standards developed by the American Bankers Association. DES is used to encrypt personal identification numbers (PINs) and account transactions carried out by automated teller machines (ATMs). DES is also used by the Clearing House Interbank Payments System (CHIPS) to authenticate transactions involving over $\$ 1.5 \times 10^{12}$ per week.

DES is also widely used in government organizations, such as the Department of Energy, the Justice Department, and the Federal Reserve System.

### 3.4.1 DES Modes of Operation

Four modes of operation have been developed for DES: electronic codebook mode (ECB), cipher feedback mode (CFB), cipher block chaining mode (CBC)

FIGURE 3.4
CBC mode
and output feedback mode (OFB).
ECB mode corresponds to the usual use of a block cipher: given a sequence $x_{1} x_{2} \ldots$ of 64-bit plaintext blocks, each $x_{i}$ is encrypted with the same key $K$, producing a string of ciphertext blocks, $y_{1} y_{2} \ldots$.

In CBC mode, each ciphertext block $y_{i}$ is $x$-ored with the next plaintext block $x_{i+1}$ before being encrypted with the key $K$. More formally, we start with a 64 -bit initialization vector IV, and define $y_{0}=$ IV. Then we construct $y_{1}, y_{2}, \ldots$ from the rule $y_{i}=e_{K}\left(y_{i-1} \oplus x_{i}\right), i \geq 1$. The use of CBC mode is depicted in Figure 3.4.

FIGURE 3.5

## CFB mode

In OFB and CFB modes, a keystream is generated which is then x -ored with the plaintext (i.e., it operates as a stream cipher, cf. Section 1.1.7). OFB is actually a synchronous stream cipher: the keystream is produced by repeatedly encrypting a 64-bit initialization vector, IV. We define $z_{0}=\mathrm{IV}$, and then compute the keystream $z_{1} z_{2} \ldots$ from the rule $z_{i}=e_{K}\left(z_{i-1}\right), i \geq 1$. The plaintext sequence $x_{1} x_{2} \ldots$ is then encrypted by computing $y_{i}=x_{i} \oplus z_{i}, i \geq 1$.

In CFB mode, we start with $y_{0}=$ IV (a 64 -bit initialization vector) and we produce the keystream element $z_{i}$ by encrypting the previous ciphertext block. That is, $z_{i}=e_{K}\left(y_{i-1}\right), i \geq 1$. As in OFB mode, $y_{i}=x_{i} \oplus z_{i}, i \geq 1$. The use of CFB is depicted in Figure 3.5 (note that the DES encryption function $e_{K}$ is used for both encryption and decryption in CFB and OFB modes).

There are also variations of OFB and CFB mode called $k$-bit feedback modes ( $1 \leq k \leq 64$ ). We have described the 64 -bit feedback modes here. 1-bit and 8-bit feedback modes arc often used in practice for encrypting data one bit (or byte) at a time.

## Previous Chapter Previous Page Home Next page Next Chapter

The four modes of operation have different advantages and disadvantages. In ECB and OFB modes, changing one 64-bit plaintext block, $x_{i}$, causes the corresponding ciphertext block, $y_{i}$, to be altered, but other ciphertext blocks are not affected. In some situations this might be a desirable property. For example, OFB mode is often used to encrypt satellite transmissions.

On the other hand, if a plaintext block $x_{i}$ is changed in CBC and CFB modes, then $y_{i}$ and all subsequent ciphertext blocks will be affected. This property means that CBC and CFB modes are useful for purposes of authentication. More specifically, these modes can be used to produce a message authentication code, or MAC. The MAC is appended to a sequence of plaintext blocks, and is used to convince Bob that the given sequence of plaintext originated with Alice and was not tampered with by Oscar. Thus the MAC guarantees the integrity (or authenticity) of a message (but it does not provide secrecy, of course).

We will describe how CBC mode is used to produce a MAC. We begin with the initialization vector IV consisting of all zeroes. Then construct the ciphertext blocks $y_{1}, \ldots, y_{n}$ with key $K$, using CBC mode. Finally, define the MAC to be $y_{n}$. Then Alice transmits the sequence of plaintext blocks, $x_{1} \ldots x_{n}$, along with the MAC. When Bob receives $x_{1} \ldots x_{n}$, he can reconstruct $y_{1}, \ldots, y_{n}$ using the (secret) key $K$, and verify that $y_{n}$ is the same as the MAC that he received.

Note that Oscar cannot produce a valid MAC since he does not know the key $K$ being used by Alice and Bob. Further, if Oscar intercepts a sequence of plaintext blocks $x_{1} \ldots x_{n}$, and changes one or more of them, then it is highly unlikely that Ocsar can change the MAC so that it will be accepted by Oscar.

It is often desirable to combine authenticity and secrecy. This could be done as follows: Alice first uses key $K_{1}$ to produce a MAC for $x_{1} \ldots x_{n}$. Then she defines $x_{n+1}$ to be the MAC, and she encrypts the sequence $x_{1} \ldots x_{n+1}$ using a second key, $K_{2}$, yielding $y_{1} \ldots y_{n+1}$. When Bob receives $y_{1} \ldots y_{n+1}$, he first decrypts (using $K_{2}$ ) and then checks that $x_{n+1}$ is the MAC for $x_{1} \ldots x_{n}$ using $K_{1}$.

Alternatively, Alice could use $K_{1}$ to encrypt $x_{1} \ldots x_{n}$, obtaining $y_{1} \ldots y_{n}$, and then use $K_{2}$ to produce a MAC $y_{n+1}$ for $y_{1} \ldots y_{n}$. Bob would use $K_{2}$ to verify the MAC, and then use $K_{1}$ to decrypt $y_{1} \ldots y_{n}$.

### 3.5 A Time-memory Trade-off

In this section, we describe an interesting time-memory tradeoff for a chosen plaintext attack. Recall that in a chosen plaintext attack, Oscar obtains a plaintextciphertext pair produced using the (unknown) key $K$. So Oscar has $x$ and $y$, where $y=\epsilon_{K}(x)$, and he wants to determine $K$.

A feature of this time-memory trade-off is that it does not depend on the "structure" of DES in any way. The only aspects of DES that are relevant to the attack are that plaintexts and ciphertexts have 64 bits, while keys have 56 bits.
3.5. A TIME-MEMORY TRADE-OFF

FIGURE 3.6
Computation of $X(i, j)$

| $X(1,0)$ | $\xrightarrow{g}$ | $X(1,1)$ | $\xrightarrow{g}$ | $\ldots$ | $\xrightarrow{g}$ | $X(1, t)$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| $X(2,0)$ | $\xrightarrow{g}$ | $X(2,1)$ | $\xrightarrow{g}$ | $\ldots$ | $\xrightarrow{g}$ | $X(2, t)$ |
| $\vdots$ |  |  |  |  |  | $\vdots$ |
| $X(m, 0)$ | $\xrightarrow{g}$ | $X(m, 1)$ | $\xrightarrow{g}$ | $\ldots$ | $\xrightarrow{g}$ | $X(m, t)$ |

We have already discussed the idea of exhaustive search: given a plaintextciphertext pair, try all $2^{56}$ possible keys. This requires no memory but, on average, $2^{55}$ keys will be tried before the correct one is found. On the other hand, for a given plaintext $x$, Oscar could precompute $y_{K}=e_{K}(x)$ for all $2^{56}$ keys $K$, and construct a table of ordered pairs $\left(y_{K}, K\right)$, sorted by their first coordinates. At a later time, when Oscar obtains the ciphertext $y$ which is an encryption of plaintext $x$, he looks up the value $y$ in the table, immediately obtaining the key $K$. Now the actual determination of the key requires only constant time, but we have a large memory requirement and a large precomputation time. (Note that this approach would yield no advantage in total computation time if only one key is to be found, since constructing the table takes at least as much time as an exhaustive search. The advantage occurs when several keys are to be found over a period of time, since the same table can be used in each case.)

The time-memory trade-off combines provides a smaller computation time than exhaustive search with a smaller memory requirement than table look-up. The algorithm can be described in terms of two parameters $m$ and $t$, which are positive integers. The algorithm requires a reduction function $R$ which reduces a bitstring of length 64 to one of length 56. ( $R$ might just discard eight of the 64 bits, for example.) Let $x$ be a fixed plaintext string of length 64. Define the function $g\left(K_{0}\right)=R\left(e_{K_{0}}(x)\right)$ for a bitstring $K_{0}$ of length 56 . Note that $g$ is a function that maps 56 bits to 56 bits.

In the pre-processing stage, Oscar chooses $m$ random bitstrings of length 56, denoted $X(i, 0), 1 \leq i \leq m$. Oscar computes $X(i, j)$ for $1 \leq j \leq t$ according to the recurrence relation $X(i, j)=g(X(i, j-1)), 1 \leq i \leq m, 1 \leq j \leq t$, as indicated in Figure 3.6.

Then Oscar constructs a table of ordered pairs $T=(X(i, t), X(i, 0))$, sorted by their first coordinate (i.e., only the first and last columns of $X$ are stored).

At a later time, Oscar obtains a ciphertext $y$ which is an encryption of the chosen plaintext $x$ (as before). He again wants to determine $K$. He is going to determine if $K$ is in the first $t$ columns of the array $X$, but he will do this by looking only at the table $T$.

Suppose that $K=X(i, t-j)$ for some $j, 1 \leq j \leq t$ (i.e., suppose that $K$ is in the first $t$ columns of $X$ ). Then it is clear that $g^{j}(K)=X(i, t)$, where $g^{j}$ denotes

FIGURE 3.7
DES time-memory trade-off

1. compute $y_{1}=R(y)$
2. for $j=1$ to $t$ do
3. if $y_{j}=X(i, t)$ for some $i$ then
4. compute $X(i, t-j)$ from $X(i, 0)$ by iterating the $g$

$$
\text { function } t-j \text { times }
$$

5. if $y=e_{X(i, t-j)}(x)$ then set $K=X(i, t-j)$ and QUIT
6. compute $y_{j+1}=g\left(y_{j}\right)$
the function obtained by iterating $g, j$ times. Now, observe that

$$
\begin{aligned}
g^{j}(K) & =g^{j-1}(g(K)) \\
& =g^{j-1}\left(R\left(e_{K}(x)\right)\right. \\
& =g^{j-1}(R(y))
\end{aligned}
$$

Suppose we compute $y_{j}, 1 \leq j \leq t$, from the recurrence relation

$$
y_{j}= \begin{cases}R(y) & \text { if } j=1 \\ g\left(y_{j-1}\right) & \text { if } 2 \leq j \leq t\end{cases}
$$

Then it follows that $y_{j}=X(i, t)$ if $K=X(i, t-j)$. However, note that $y_{j}=X(i, t)$ is not sufficient to ensure that $K=X(i, t-j)$. This is because the reduction function $R$ is not an injection: The domain of $R$ has cardinality $2^{64}$ and the range of $R$ has cardinality $2^{56}$, so, on average, there are $2^{8}=256$ pre-images of any given bitstring of length 56 . So we need to check whether $y=e_{X(i, t-j)}(x)$, to see if $X(i, t-j)$ is indeed the key. We did not store the value $X(i, t-j)$, but we can easily re-compute it from $X(i, 0)$ by iterating the $g$ function $t-j$ times.

Oscar proceeds according to the algorithm presented in Figure 3.7.
By analyzing the probability of success for the algorithm, it can be shown that if $m t^{2} \approx N=2^{56}$, then the probability that $K=X(i, t-j)$ for some $i, j$ is about $0.8 \mathrm{mt} / N$. The factor 0.8 accounts for the fact that the numbers $X(i, t)$ may not all be distinct. It is suggested that one should take $m \approx t \approx N^{1 / 3}$ and construct about $N^{1 / 3}$ tables, each using a different reduction function $R$. If this is done, the memory requirement is $112 \times N^{2 / 3}$ bits (since we need to store $2 \times N^{2 / 3}$ integers, each of which has 56 bits). The precomputation time is easily seen to be $O(N)$.

The running time is a bit more dificult to analyze. First, note that step 3 can be implemented to run in (expected) constant time (using hash coding) or (worst-
case) time $O(\log m)$ using a binary search. If step 3 is never satisfied (i.e., the search fails), then the running time is $O\left(N^{2 / 3}\right)$. A more detailed analysis shows that even when the running time of steps 4 and 5 is taken into account, the expected running time increases by only a constant factor.

### 3.6 Differential Cryptanalysis

One very well-known attack on DES is the method of "differential cryptanalysis" introduced by Biham and Shamir. This is a chosen-plaintext attack. Although it does not provide a practical method of breaking the usual 16 -round DES, it does succeed in breaking DES if the number of rounds of encryption is reduced. For instance, 8 -round DES can be broken in only a couple of minutes on a small personal computer.

We will now describe the basic ideas used in this technique. For the purposes of this attack, we can ignore the initial permutation IP and its inverse (it has no effect on cryptanalysis). As mentioned above, we consider DES restricted to $n$ rounds, for various values of $n \leq 16$. So, in this setting, we will regard $L_{0} R_{0}$ as the plaintext, and $L_{n} R_{n}$ as the ciphertext, in an $n$-round DES. (Note also that we are not inverting $L_{n} R_{n}$.)

Differential cryptanalysis involves comparing the x-or (exclusive-or) of two plaintexts to the x -or of the corresponding two ciphertexts. In general, we will be looking at two plaintexts $L_{0} R_{0}$ and $L_{0}^{*} R_{0}^{*}$ with a specified x-or value $L_{0}^{\prime} R_{0}^{\prime}=$ $L_{0} R_{0} \oplus L_{0}^{*} R_{0}^{*}$. Throughout this discussion, we will use prime markings (') to indicate the $x$-or of two bitstrings.

DEFINITION 3.1 Let $S_{j}$ be a particular $S$-box $(1 \leq j \leq 8)$. Consider an (ordered) pair of bitstrings of length six, say $\left(B_{j}, B_{j}^{*}\right)$. We say that the input $x$-or (of $S_{j}$ ) is $B_{j} \oplus B_{j}^{*}$ and the output x-or $\left(\right.$ of $\left.S_{j}\right)$ is $S_{j}\left(B_{j}\right) \oplus S_{j}\left(B_{j}^{*}\right)$.

Note that an input x -or is a bitstring of length six and an output x -or is a bitstring of length four.

DEFINITION 3.2 For any $B_{j}^{\prime} \in\left(\mathbb{Z}_{2}\right)^{6}$, define the set $\Delta\left(B_{j}^{\prime}\right)$ to consist of the ordered pairs $\left(B_{j}, B_{j}^{*}\right)$ having inputx-or $B_{j}^{\prime}$.

It is easy to see that any set $\Delta\left(B_{j}^{\prime}\right)$ contains $2^{6}=64$ pairs, and that

$$
\Delta\left(B_{j}^{\prime}\right)=\left\{\left(B_{j}, B_{j} \oplus B_{j}^{\prime}\right): B_{j} \in\left(\mathbb{Z}_{2}\right)^{6}\right\}
$$

For each pair in $\Delta\left(B_{j}^{\prime}\right)$, we can compute the output x-or of $S_{j}$ and tabulate the resulting distribution. There are 64 output x -ors, which are distributed among

## CHAPTER 3. THE DATA ENCRYPTION STANDARD

$2^{4}=16$ possible values. The non-uniformity of these distributions will be the basis for the attack.

## Example 3.1

Suppose we consider the first S -box, $S_{\mathrm{I}}$, and the input x -or 110100 . Then

$$
\Delta(110100)=\{(000000,110100),(000001,110101), \ldots,(111111,001011)\} .
$$

For each ordered pair in the set $\Delta(110100)$, we compute output x -or of $S_{1}$. For example, $S_{1}(000000)=E_{16}=1110$ and $S_{1}(110100)=9_{16}=1001$, so the output x-or for the pair $(000000,110100)$ is 0111 .

If this is done for all 64 pairs in $\Delta(110100)$, then the following distribution of output x -ors is obtained:

| 0000 | 0001 | 0010 | 0011 | 0100 | 0101 | 0110 | 0111 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 0 | 8 | 16 | 6 | 2 | 0 | 0 | 12 |

| 1000 | 1001 | 1010 | 1011 | 1100 | 1101 | 1110 | 1111 |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 6 | 0 | 0 | 0 | 0 | 8 | 0 | 6 |

[

In Example 3.1, only eight of the 16 possible output x-ors actually occur. This particular example has a very non-uniform distribution. In general, if we fix an S-box $S_{j}$ and an input x-or $B_{j}^{\prime}$, then on average, it turns out that about $75-80 \%$ of the possible output $x$-ors actually occur.

It will be convenient to have some notation to describe these distributions and how they arise, so we make the following definitions.

DEFINITION 3.3 For $1 \leq j \leq 8$, and for bitstrings $B_{j}^{\prime}$ of length six and $C_{j}^{\prime}$ of length four, define

$$
I N_{j}\left(B_{j}^{\prime}, C_{j}^{\prime}\right)=\left\{B_{j} \in\left(\mathbb{Z}_{2}\right)^{6}: S_{j}\left(B_{j}\right) \oplus S_{j}\left(B_{j} \oplus B_{j}^{\prime}\right)=C_{j}^{\prime}\right\}
$$

and

$$
N_{j}\left(B_{j}^{\prime}, C_{j}^{\prime}\right)=\left|I N_{j}\left(B_{j}^{\prime}, C_{j}^{\prime}\right)\right|
$$

$N_{j}\left(B_{j}^{\prime}, C_{j}^{\prime}\right)$ counts the number of pairs with input x-or equal to $B_{j}^{\prime}$ which have output x-or equal to $C_{j}^{\prime}$ for the $S$-box $S_{j}$. The actual pairs having the specified input x -ors and giving rise to the specified output x -ors can be obtained from the set $I N_{j}\left(B_{j}^{\prime}, C_{j}^{\prime}\right)$. Observe that this set can be partitioned into $N_{j}\left(B_{j}^{\prime}, C_{j}^{\prime}\right) / 2$ pairs, each of which has (input) x-or equal to $B_{j}^{\prime}$.

Note that the distribution tabulated in Example 3.1 consists of the values $N_{1}\left(110100, C_{1}^{\prime}\right), C_{1}^{\prime} \in\left(\mathbb{Z}_{2}\right)^{4}$. The sets $I N_{1}\left(110100, C_{1}^{\prime}\right)$ are listed in Figure 3.8.

## FIGURE 3.8

| 0100 | 010011,100111 |
| 0101 |  |
| 0110 | $000000,001000,001101,010111$ <br> $011000,011101,100011,101001$ <br> $101100,110100,111001,111100$ |
| 0111 | $001001,001100,011001,101101$ <br> 111000,111101 |
| 1000 |  |
| 1001 |  |
| 1010 |  |
| 1011 | $000110,010000,010110,011100$ <br> $100010,100100,101000,110010$ |
| 1100 | $000111,001010,001011,110011$ <br> 1101 |
| 1110 | 1111 |

For each of the eight S-boxes, there are 64 possible input $x$-ors. Thus, there are 512 distributions which can be computed. These could easily be tabulated by computer.

Recall that the input to the S -boxes in round $i$ is formed as $B=E \oplus J$, where $E=\mathrm{E}\left(R_{i-1}\right)$ is the expansion of $R_{i-1}$ and $J=K_{i}$ consists of the key bits for round $i$. Now, the input x -or (for all eight S -boxes) can be computed as follows:

$$
\begin{aligned}
B \oplus B^{*} & =(E \oplus J) \oplus\left(E^{*} \oplus J\right) \\
& =E \oplus E^{*} .
\end{aligned}
$$

It is very important to observe that the input x -or does not depend on the key bits
$J$. (However, the output x-or certainly does depend on these key bits.)
We will write each of $B, E$ and $J$ as the concatenation of eight 6 -bit strings:

$$
\begin{aligned}
B & =B_{1} B_{2} B_{3} B_{4} B_{5} B_{6} B_{7} B_{8} \\
E & =E_{1} E_{2} E_{3} E_{4} E_{5} E_{6} E_{7} E_{8} \\
J & =J_{1} J_{2} J_{3} J_{4} J_{5} J_{6} J_{7} J_{8},
\end{aligned}
$$

and we write $B^{*}, E^{*}, J^{*}$ in a similar way. Let us suppose for the moment that we know the values $E_{j}$ and $E_{j}^{*}$ for some $j, 1 \leq j \leq 8$, and the value of the output x-or for $S_{j}, C_{j}^{\prime}=S_{j}\left(B_{j}\right) \oplus S_{j}\left(B_{j}^{*}\right)$. Then it must be the case that

$$
E_{j} \oplus J_{j} \in I N_{j}\left(E_{j}^{\prime}, C_{j}^{\prime}\right)
$$

where $E_{j}^{\prime}=E_{j} \oplus E_{j}^{*}$.
Suppose we define a set test ${ }_{j}$ as follows:
DEFINITION 3.4 Suppose $E_{j}$ and $E_{j}^{*}$ are bitstrings of length six, and $C_{j}^{\prime}$ is a bitstring of length four. Define

$$
\operatorname{test}_{j}\left(E_{j}, E_{j}^{*}, C_{j}^{\prime}\right)=\left\{B_{j} \oplus E_{j}: B_{j} \in I N_{j}\left(E_{j}^{\prime}, C_{j}^{\prime}\right)\right\}
$$

where $E_{j}^{\prime}=E_{j} \oplus E_{j}^{*}$.
That is, we take the x-or of $E_{j}$ with every element of the set $I N_{j}\left(E_{j}^{\prime}, C_{j}^{\prime}\right)$.
The following result is an immediate consequence of the discussion above.

## THEOREM 3.1

Suppose $E_{j}$ and $E_{j}^{*}$ are two inputs to the $S$-box $S_{j}$, and the outputx-orfor $S_{j}$ is $C_{j}^{\prime}$.
Denote $E_{j}^{\prime}=E_{j} \oplus E_{j}^{*}$. Then the key bits $J_{j}$ occur in the set test ${ }_{j}\left(E_{j}, E_{j}^{*}, C_{j}^{\prime}\right)$.
Observe that there will be exactly $N_{j}\left(E_{j}^{\prime}, C_{j}^{\prime}\right)$ bitstrings of length six in the set test ${ }_{j}\left(F_{j}, E_{j}^{*}, C_{j}^{\prime}\right)$; the correct value of $J_{j}$ must be one of these possibilities.

Example 3.2
Suppose $E_{1}=000001, E_{1}^{*}=110101$ and $C_{1}^{\prime}=1101$. Since $N_{1}(110100,1101)=$ 8, there will be exactly eight bitstrings in the set test ${ }_{1}(000001,110101,1101)$. From Figure 3.8, we see that

$$
\begin{aligned}
& I N_{1}(110100,1101)= \\
& \quad\{000110,010000,010110,011100,100010,100100,101000,110010\}
\end{aligned}
$$

Hence,

$$
\begin{aligned}
& \text { test }_{1}(000001,110101,1101)= \\
& \quad\{000111,010001,010111,011101,100011,100101,101001,110011\} .
\end{aligned}
$$

If we have a second such triple $E_{1}, E_{1}^{*}, C_{1}^{\prime}$, then we can obtain a second set test $t_{1}$ of possible values for the kcybits in $J_{1}$. The true value of $J_{1}$ must be in the intersection of both sets. If we have several such triples, then we can quickly determine the key bits in $J_{1}$. One straightforward way to do this is to maintain an array of 64 counters, representing the 64 possibilities for the six key bits in $J_{1}$. A counter is incremented every time the corresponding key bits occur in a set test ${ }_{1}$ for a particular triple. Given $t$ triples, we hope to find a unique counter which has the value $t$; this will correspond to the true value of the keybits in $J_{1}$.

### 3.6.1 An Attack on a 3-round DES

Let's now see how the ideas of the previous section can be applied in a chosen plaintext attack of a 3-round DES. We will begin with a pair of plaintexts and corresponding ciphertexts: $L_{0} R_{0}, L_{0}^{*} R_{0}^{*}, L_{3} R_{3}$ and $L_{3}^{*} R_{3}^{*}$. We can express $R_{3}$ as follows:

$$
\begin{aligned}
R_{3} & =L_{2} \oplus f\left(R_{2}, K_{3}\right) \\
& =R_{\mathbf{1}} \oplus f\left(R_{2}, K_{3}\right) \\
& =L_{0} \oplus f\left(R_{0}, K_{1}\right) \oplus f\left(R_{2}, K_{3}\right)
\end{aligned}
$$

$R_{3}^{*}$ can be expressed in a similar way, and hence

$$
R_{3}^{\prime}=L_{0}^{\prime} \oplus f\left(R_{0}, K_{1}\right) \oplus f\left(R_{0}^{*}, K_{1}\right) \oplus f\left(R_{2}, K_{3}\right) \oplus f\left(R_{2}^{*}, K_{3}\right)
$$

Now, suppose we have chosen the plaintexts so that $R_{0}=R_{0}^{*}$, i.e., so that

$$
R_{0}^{\prime}=00 \ldots 0
$$

Then $f\left(R_{0}, K_{1}\right)=f\left(R_{0}^{*}, K_{1}\right)$ and so

$$
R_{3}^{\prime}=L_{0}^{\prime} \oplus f\left(R_{2}, K_{3}\right) \oplus f\left(R_{2}^{*}, K_{3}\right)
$$

At this point, $R_{3}^{\prime}$ is known since it can be computed from the two ciphertexts, and $L_{0}^{\prime}$ is known since it can be computed from the two plaintexts. This means that we can compute $f\left(R_{2}, K_{3}\right) \oplus f\left(R_{2}^{*}, K_{3}\right)$ from the equation

$$
f\left(R_{2}, K_{3}\right) \oplus f\left(R_{2}^{*}, K_{3}\right)=R_{3}^{\prime} \oplus L_{0}^{\prime}
$$

Now, $f\left(R_{2}, K_{3}\right)=\mathrm{P}(C)$ and $f\left(R_{2}^{*}, K_{3}\right)=\mathrm{P}\left(C^{*}\right)$, where $C$ and $C^{*}$, respectively, denote the two outputs of the eight $S$-boxes (recall that P is a fixed, publicly known permutation). Hence,

$$
\mathrm{P}(C) \oplus \mathrm{P}\left(C^{*}\right)=R_{3}^{\prime} \oplus L_{0}^{\prime}
$$

FIGURE 3.9
Differential attack on 3-round DES

```
    Input: \(L_{0} R_{0}, L_{0}^{*} R_{0}^{*}, L_{3} R_{3}\) and \(L_{3}^{*} R_{3}^{*}\), where \(R_{0}=R_{0}^{*}\)
1. compute \(C^{\prime}=\mathrm{P}^{-1}\left(R_{3}^{\prime} \oplus L_{0}^{\prime}\right)\)
2. compute \(E=\mathrm{E}\left(L_{3}\right)\) and \(E^{*}=\mathrm{E}\left(L_{3}^{*}\right)\)
3. for \(j=1\) to 8 do
    compute test \(_{j}\left(E_{j}, E_{j}^{*}, C_{j}^{\prime}\right)\)
```

and consequently

$$
\begin{equation*}
C^{\prime}=C \oplus C^{*}=\mathrm{P}^{-1}\left(R_{3}^{\prime} \oplus L_{0}^{\prime}\right) \tag{3.1}
\end{equation*}
$$

This is the output x -or for the eight S -boxes in round three.
Now, $R_{2}=L_{3}$ and $R_{2}^{*}=L_{3}^{*}$ are also known (they are part of the ciphertexts). Hence, we can compute

$$
\begin{equation*}
E=\mathrm{E}\left(L_{3}\right) \tag{3.2}
\end{equation*}
$$

and

$$
\begin{equation*}
E^{*}=\mathrm{E}\left(L_{3}^{*}\right) \tag{3.3}
\end{equation*}
$$

using the publicly known expansion function E . These are the inputs to the S -boxes for round three. So, we now know $E, E^{*}$, and $C^{\prime}$ for the third round, and we can proceed, as in the previous section, to construct the sets test ${ }_{1}, \ldots$, test ${ }_{8}$ of possible values for the key bits in $J_{1}, \ldots, J_{8}$.

A pseudo-code description of this algorithm is given in Figure 3.9. The attack will use several such triples $E, E^{*}, C^{\prime}$. We set up eight arrays of counters, and thereby determine the 48 bits in $K_{3}$, the key for the third round. The 56 bits in the key can then be computed by an exhaustive search of the $2^{8}=256$ possibilities for the remaining eight key bits.

Let's look at an example to illustrate.

## Example 3.3

Suppose we have the following three pairs of plaintexts and ciphertexts, where the plaintexts have the specified $x$-ors, that are encrypted using the same key. We use a hexadecimal representation, for brevity:

| plaintext | ciphertext |
| :---: | :---: |
| 748502 CD 38451097 | 03C70306D8A09F10 |
| 3874756438451097 | 78560A0960E6D4CB |
| 486911026ACDFF31 | 45FA285BE5ADC730 |
| 375BD31F6ACDFF31 | 134F7915AC253457 |
| 357418DA013FEC86 | D8A31B2F28BBC5CF |
| 12549847013FEC86 | 0F317AC2B23CB944 |

From the first pair, we compute the $S$-box inputs (for round 3) from Equations (3.2) and (3.3). They are:

$$
\begin{aligned}
E & =000000000111111000001110100000000110100000001100 \\
E^{*} & =101111110000001010101100000001010100000001010010
\end{aligned}
$$

The S-box output x-or is calculated using Equation (3.1) to be:

$$
C^{\prime}=10010110010111010101101101100111 .
$$

From the second pair, we compute the $S$-box inputs to be

$$
\begin{aligned}
E & =101000001011111111110100000101010000001011110110 \\
E^{*} & =100010100110101001011110101111110010100010101010
\end{aligned}
$$

and the S -box output x -or is

$$
C^{\prime}=10011100100111000001111101010110 .
$$

From the third pair, the S-box inputs are

$$
\begin{aligned}
E & =111011110001010100000110100011110110100101011111 \\
E^{*} & =000001011110100110100010101111110101011000000100
\end{aligned}
$$

and the S -box output x -or is

$$
C^{\prime}=11010101011101011101101100101011
$$

Next, we tabulate the values in the cight counter arrays for each of the three pairs. We illustrate the procedure with the counter array for $J_{1}$ from the first pair. In this pair, we have $E_{1}^{\prime}=101111$ and $C_{1}^{\prime}=1001$. The set

$$
I N_{1}(101111,1001)=\{000000,000111,101000,101111\}
$$

Since $E_{1}=000000$, we have that

$$
J_{1} \in \text { test }_{1}(000000,101111,1001)=\{000000,000111,101000,101111\}
$$

Hence, we increment the values $0,7,40$, and 47 in the counter array for $J_{1}$.

The final tabulations are now presented. If we think of a bit-string of length six as being the binary representation of an integer between 0 and 63 , then the 64 values correspond to the counts of $0,1, \ldots, 63$. The counter arrays are as follows:

| $J_{1}$ |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |  |  |
|  | 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | 1 | 1 |  | 0 |  |  |
| 0 | 1 | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 |  |  |
| 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |  |  |

| $J_{2}$ |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 0 | 0 | 0 | 1 | 0 | 3 | 0 | 0 | 1 | 0 | 0 | 1 | 0 | 0 | 0 |
| 0 | 1 | 0 | 0 | 0 | 2 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 |
| 0 | 0 |  |  |  |  |  |  |  |  |  |  |  |  |  |
| 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 1 | 0 | 1 | 0 | 0 | 0 | 1 |
| 0 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 0 | 2 | 0 | 0 |
| 0 | 0 |  |  |  |  |  |  |  |  |  |  |  |  |  |

| $J_{3}$ |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 |
|  | 0 | 0 | 3 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |  | 1 | 1 |
|  | 2 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 1 |  | 1 | 0 | 0 |
| 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 0 | 0 |  |

| $J_{4}$ |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- | :--- |
| 3 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 2 | 2 | 0 | 0 | 0 | 0 |
| 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 1 | 0 | 1 | 1 |
| 1 | 1 | 1 | 0 | 1 | 0 | 0 | 0 | 0 | 1 | 1 | 1 | 0 | 0 | 1 | 0 |
| 0 | 0 | 0 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 2 | 1 |

| $J_{5}$ |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 0 | 0 | 0 | 0 | 0 | 1 | 0 |  | 0 | 0 | 1 | 0 | 0 | 0 | 0 | 0 |
|  | 0 | 0 | 0 | 2 | 0 | 0 | 0 |  | 3 | 0 | 0 | 0 | 0 | 0 | 0 |  |
|  | 0 | 0 | 0 | 0 | 0 | 0 |  |  |  | 0 | 0 | 0 | 0 | 0 | 0 |  |
|  | 0 | 2 | 0 | 0 | 0 | 0 | 0 |  |  |  |  |  |  |  |  |  |

| $J_{6}$ |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 |  |  | 0 | 1 | 1 | 0 | 0 | 3 | 0 | 0 | 0 | 0 | 1 | 0 |  | 0 | 1 |
| 0 |  |  | 0 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 | 0 | 0 |  | 0 | 0 |
| 0 |  |  | 0 | 0 | 1 | 1 | 0 | 1 | 0 | 0 | 0 | 0 | 0 | 0 |  | 0 | 0 |
| 1 | 0 |  | 0 | 1 | 1 | 0 | 1 | 1 | 0 | 0 | 0 | 0 | 0 | 0 |  | 0 | 0 |

### 3.6. DIFFERENTIAL CRYPTANALYSIS

| $J_{8}$ |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | 0 | 0 | 0 | 0 | 0 | 0 |  | 0 | 0 | 0 | 0 |  | 0 | 0 | 0 |  | 0 | 0 |
|  | 0 | 0 | 0 |  | 0 | 0 |  | 0 | 0 | 0 | 0 |  | 0 |  | 0 |  | 0 | 0 |
|  | 0 | 0 | 0 | 0 | 0 | 0 |  | 0 | 1 | 0 | 1 |  | 0 | 0 | 1 |  | 0 | 1 |
| 0 | 3 | 0 | 0 | 0 | 0 | 1 |  | 0 | 0 | 0 | 0 |  | 0 | 0 | 0 |  | 0 | 0 |

In each of the eight counter arrays, there is a unique counter having the value 3. The positions of these counters determine the key bits in $J_{1}, \ldots, J_{8}$. These positions are (respectively): $47,5,19,0,24,7,7,49$. Converting these integers to binary, we obtain $J_{1}, \ldots, J_{8}$ :

$$
\begin{aligned}
& J_{1}=101111 \\
& J_{2}=000101 \\
& J_{3}=010011 \\
& J_{4}=000000 \\
& J_{5}=011000 \\
& J_{6}=000111 \\
& J_{7}=000111 \\
& J_{8}=110001
\end{aligned}
$$

We can now construct 48 bits of the key, by looking at the key schedule for round 3. It follows that $K$ has the form

$$
\begin{array}{llll}
0001101 & 0110001 & 01 ? 01 ? 0 & 1 ? 00100 \\
0101001 & 0000 ? ? 0 & 111 ? 11 ? & ? 100011
\end{array}
$$

where parity bits are omitted and "?" denotes an unknown key bit. The complete key (in hexadecimal, including parity bits), is:

### 3.6.2 An Attack on a 6-round DES

We now describe an extension of these ideas to a probabilistic attack on a 6-round DES. The idea is to carefully choose a pair of plaintexts with a specified $x$-or, and then to determine the probabilities of a specified sequence of $x$-ors through the rounds of encryption. We need to define an important concept now.

DEFINITION 3.5 Let $n \geq 1$ be an integer. An n-round characteristic is a list of the form

$$
L_{0}^{\prime}, R_{0}^{\prime}, L_{1}^{\prime}, R_{1}^{\prime}, p_{1}, \ldots, L_{n}^{\prime}, R_{n}^{\prime}, p_{n}
$$

which satisfies the following properties:

1. $L_{i}^{\prime}=R_{i-1}^{\prime}$ for $1 \leq i \leq n$.
2. Let $1 \leq i \leq n$, and let $L_{i-1}, R_{i-1}$ and $L_{i-1}^{*}, R_{i-1}^{*}$ be chosen such that $L_{i-1} \oplus L_{i-1}^{*}=L_{i-1}^{\prime}$ and $R_{i-1} \oplus R_{i-1}^{*}=R_{i-1}^{\prime}$. Suppose $L_{i}, R_{i}$ and $L_{i}^{*}, R_{i}^{*}$ are computed by applying one round of DES encryption. Then the probability that $L_{i} \oplus L_{i}^{*}=L_{i}^{\prime}$ and $R_{i} \oplus R_{i}^{*}=R_{i}^{\prime}$ is precisely $p_{i}$. (Note that this prohability is computed over all possible 48-tuples $J=J_{1} \ldots J_{8}$.)

The probability of the characteristic is defined to be the product $p=p_{1} \times \ldots \times p_{n}$.
REMARK Suppose we choose $L_{0}, R_{0}$ and $L_{0}^{*}, R_{0}^{*}$ so that $L_{0} \oplus L_{0}^{*}=L_{0}^{\prime}$ and $R_{0} \oplus R_{0}^{*}=R_{0}^{\prime}$ and we apply $n$ rounds of DES encryption, obtaining $L_{1}, \ldots, L_{n}$ and $R_{1}, \ldots, R_{n}$. Then we cannot claim that the probability that $L_{i} \oplus L_{i}^{*}=L_{i}^{\prime}$ and $R_{i} \oplus R_{i}^{*}=R_{i}^{\prime}$ for all $i(1 \leq i \leq n)$ is $p_{1} \times \ldots \times p_{n}$. This is because the 48-tuples in the key schedule $K_{1}, \ldots, K_{n}$, are not mutually independent. (If these $n 48$-tuples were chosen independently at random, then the assertion would be true.) But we nevertheless expect $p_{1} \times \ldots \times p_{n}$ to be a fairly accurate estimate of this probability.

We also need to recognize that the probabilities $p_{i}$ in a characteristic are defined with respect to an arbitrary (but fixed) pair of plaintexts having a specified $x$ or, where the 48 key bits for one round of DES encryption vary over all $2^{48}$ possibilities. However, a cryptanalyst is attempting to determine a fixed (but unknown) key. He is going to choose plaintexts at random (such that they have specified x -ors), hoping that the probabilities that the x -ors during the $n$ rounds of encryption agree with the $x$-ors specified in the characteristic are fairly close to $p_{1}, \ldots, p_{n}$, respectively.

As a simple example, we present in Figure 3.10 a 1-round characteristic which was the basis of the attack on the 3-round DES (as before, we use hexadecimal representations). We depict another 1 -round characteristic in Figure 3.11.

Let's look at the characteristic in Figure 3.11 in more detail. When $f\left(R_{0}, K_{1}\right)$ and $f\left(R_{0}^{*}, K_{1}\right)$ are computed, the first step is to expand $R_{0}$ and $R_{0}^{*}$. The resulting

FIGURE 3.10
A 1-round characteristic

| $L_{0}^{\prime}=$ anything | $R_{0}^{\prime}=00000000_{16}$ |  |
| :--- | :--- | :--- |
| $L_{1}^{\prime}=00000000_{16}$ | $R_{1}^{\prime}=L_{0}^{\prime}$ | $p=1$ |

FIGURE 3.11
Another 1-round characteristic

$$
\begin{array}{|llll|}
\hline L_{0}^{\prime}=00000000_{16} & R_{0}^{\prime}=60000000_{16} & \\
L_{1}^{\prime}=60000000_{16} & R_{1}^{\prime}=00808200_{16} & p=14 / 64 \\
\hline
\end{array}
$$

$x$-or of the two expansions is

$$
001100 \ldots 0
$$

So the input x-or to $S_{1}$ is 001100 and the input x-ors for the other seven $S$-boxes are all 000000 . The output x-ors for $S_{2}$ through $S_{8}$ will all be 0000 . The output x-or for $S_{1}$ will be 1110 with probability $14 / 64$ (since it can be computed that $N_{1}(001100,1110)=14$ ). So we obtain

$$
C^{\prime}=11100000000000000000000000000000
$$

with probability $14 / 64$. Applying P, we get

$$
\mathrm{P}(C) \oplus \mathrm{P}\left(C^{*}\right)=00000000100000001000001000000000
$$

which in hexadecimal is $00808200_{16}$. When this is x -ored with $L_{0}^{\prime}$, we get the specified $R_{1}^{\prime}$ with probability $14 / 64$. Of course $L_{1}^{\prime}=R_{0}^{\prime}$ always.

The attack on the 6-round DES is based on the 3-round characteristic given in Figure 3.12. In the 6-round attack, we will start with $L_{0} R_{0}, L_{0}^{*} R_{0}^{*}, L_{6} R_{6}$ and $L_{6}^{*} R_{6}^{*}$, where we have chosen the plaintexts so that $L_{0}^{\prime}=40080000_{16}$ and

FIGURE 3.12
A 3-round characteristic

| $L_{0}^{\prime}=40080000_{16}$ | $R_{0}^{\prime}=04000000_{16}$ |  |
| :--- | :--- | :--- | :--- |
| $L_{1}^{\prime}=04000000_{16}$ | $R_{1}^{\prime}=00000000_{16}$ | $p=1 / 4$ |
| $L_{2}^{\prime}=00000000_{16}$ | $R_{2}^{\prime}=04000000_{16}$ | $p=1$ |
| $L_{3}^{\prime}=04000000_{16}$ | $R_{3}^{\prime}=40080000_{16}$ | $p=1 / 4$ |

$R_{0}^{\prime}=04000000_{16}$. We can express $R_{6}$ as follows:

$$
\begin{aligned}
R_{6} & =L_{5} \oplus f\left(R_{5}, K_{6}\right) \\
& =R_{4} \oplus f\left(R_{5}, K_{6}\right) \\
& =L_{3} \oplus f\left(R_{3}, K_{4}\right) \oplus f\left(R_{5}, K_{6}\right) .
\end{aligned}
$$

$R_{6}^{*}$ can be expressed in a similar way, and hence we get

$$
\begin{equation*}
R_{6}^{\prime}=L_{3}^{\prime} \oplus f\left(R_{3}, K_{4}\right) \oplus f\left(R_{3}^{*}, K_{4}\right) \oplus f\left(R_{5}, K_{6}\right) \oplus f\left(R_{5}^{*}, K_{6}\right) . \tag{3.4}
\end{equation*}
$$

(Note the similarity with the 3 -round attack.)
$R_{6}^{\prime}$ is known. From the characteristic, we estimate that $L_{3}^{\prime}=04000000_{16}$ and $R_{3}^{\prime}=40080000_{16}$ with probability $1 / 16$. If this is in fact the case, then the input $x$-or for the $S$-boxes in round 4 can be computed by the expansion function to be:

$$
001000000000000001010000 \ldots 0 .
$$

The input x-ors for $S_{2}, S_{5}, S_{6}, S_{7}$ and $S_{8}$ are all 000000 , and hence the output $x$-ors are 0000 for these five $S$-boxes in round 4 . This means that we can compute the output $x$-ors of these five $S$-boxes in round 6 from Equation (3.4). So, suppose we compute

$$
C_{1}^{\prime} C_{2}^{\prime} C_{3}^{\prime} C_{4}^{\prime} C_{5}^{\prime} C_{6}^{\prime} C_{7}^{\prime} C_{8}^{\prime}=\mathrm{P}^{-1}\left(R_{6}^{\prime} \oplus 04000000_{16}\right)
$$

where each $C_{i}$ is a bitstring of length four. Then with probability $1 / 16$, it will be the case that $C_{2}^{\prime}, C_{5}^{\prime}, C_{6}^{\prime}, C_{7}^{\prime}$ and $C_{8}^{\prime}$ are respectively the output x-ors of $S_{2}, S_{5}, S_{6}$, $S_{7}$ and $S_{8}$ in round 6. The inputs to these $S$-boxes in round 6 can be computed to be $E_{2}, E_{5}, E_{6}, E_{7}$ and $E_{8}$, and $E_{2}^{*}, E_{5}^{*}, E_{6}^{*}, E_{7}^{*}$ and $E_{8}^{*}$, where

$$
E_{1} E_{2} E_{3} E_{4} E_{5} E_{6} E_{7} E_{8}=\mathrm{E}\left(R_{5}\right)=\mathrm{E}\left(L_{6}\right)
$$

and

$$
E_{1}^{*} E_{2}^{*} E_{3}^{*} E_{4}^{*} E_{5}^{*} E_{6}^{*} E_{7}^{*} E_{8}^{*}=\mathrm{E}\left(R_{5}^{*}\right)=\mathrm{E}\left(L_{6}^{*}\right)
$$

can be computed from the ciphertexts, as indicated in Figure 3.13.
We would like to determine the 30 key bits in $J_{2}, J_{5}, J_{6}, J_{7}$ and $J_{8}$ as we did in the 3 -round attack. The problem is that the hypothesized output $x$-or for round 6 is correct only with probability $1 / 16$. So $15 / 16$ of the time we will obtain random garbage rather than possible key bits. We somehow need to be able to determine the correct key from the given data, 15/16 of which is incorrect. This might not seem very promising, but fortunately our prospects are not as bleak as they initially appear.

DEFINITION 3.6 Suppose $L_{0} \oplus L_{0}^{*}=L_{0}^{\prime}$ and $R_{0} \oplus R_{0}^{*}=R_{0}^{\prime}$. We say that the pair of plaintexts $L_{0} R_{0}$ and $L_{0}^{*} R_{0}^{*}$ is right pair with respect to a characteristic if $L_{i} \oplus L_{i}^{*}=L_{i}^{\prime}$ and $R_{i} \oplus R_{i}^{*}=R_{i}^{\prime}$ for all $i, 1 \leq i \leq n$. The pair is a defined to be wrong pair, otherwise.

FIGURE 3.13
Differential attack on 6-round DES

Input: $L_{0} R_{0}, L_{0}^{*} R_{0}^{*}, L_{6} R_{6}$ and $L_{6}^{*} R_{6}^{*}$, where $L_{0}^{\prime}=40080000_{16}$ and $R_{0}^{\prime}=04000000_{16}$

1. compute $C^{\prime}=\mathrm{P}^{-1}\left(R_{6}^{\prime} \oplus 40080000_{16}\right)$
2. compute $E=\mathrm{E}\left(L_{6}\right)$ and $E^{*}=\mathrm{E}\left(L_{6}^{*}\right)$
3. for $j \in\{2,5,6,7,8\}$ do
compute test ${ }_{j}\left(E_{j}, E_{j}^{*}, C_{j}^{\prime}\right)$.

We expect that about $1 / 16$ of our pairs are right pairs and the rest are wrong pairs with respect to our 3-round characteristic.

Our strategy is to compute $E_{j}, E_{j}^{*}$, and $C_{j}^{\prime}$, as described above, and then to determine test $j_{j}\left(E_{j}, E_{j}^{*}, C_{j}^{\prime}\right)$, for $j=2,5,6,7,8$. If we start with a right pair, then the correct key bits for each $J_{j}$ will be included in the set test $t_{j}$. If the pair is a wrong pair, then the value of $C_{j}^{\prime}$ will be incorrect, and it seems reasonable to hypothesize that each set $t^{2} t_{j}$ will be essentially random.
We can often identify a wrong pair by this method: If $\mid$ test $t_{j} \mid=0$, for any $j \in\{2,5,6,7,8\}$, then we necessarily have a wrong pair. Now, given a wrong pair, we might expect that the probability that $\mid$ test ${ }_{j} \mid=0$ for a particular $j$ is approximately $1 / 5$. This is a reasonable assumption since $N_{j}\left(E_{j}^{\prime}, C_{j}^{\prime}\right)=\mid$ test ${ }_{j} \mid$ and, as mentioned earlier, the probability that $N_{j}\left(E_{j}^{\prime}, C_{j}^{\prime}\right)=0$ is approximately $1 / 5$. The probability that all five test ${ }_{j}$ 's have positive cardinality is estimated to be $.8^{5} \approx .33$, so the probability that at least one test $_{j}$ has zero cardinality is about .67. So we expect to eliminate about $2 / 3$ of the wrong pairs by this simple observation, which we call the filtering operation. The proportion of right pairs that remain after filtering is approximately $(1 / 16) /(1 / 3)=3 / 16$.

## Example 3.4

Suppose we have the following plaintext-ciphertext pair:

| plaintext | ciphertext |
| :---: | :---: |
| 86FA1C2B1F51D3BE | 1E23ED7F2F553971 |
| C6F21C2B1B51D3BE | 296DE2B687AC6340 |

Observe that $L_{0}^{\prime}=40080000_{16}$ and $R_{0}^{\prime}=04000000_{16}$. The $S$-box inputs and outputs for round 6 are computed to be the following:

| $j$ | $E_{j}$ | $E_{j}^{*}$ | $C_{j}^{\prime}$ |
| :---: | :---: | :---: | :---: |
| 2 | 111100 | 010010 | 1101 |
| 5 | 111101 | 111100 | 0001 |
| 6 | 011010 | 000101 | 0010 |
| 7 | 101111 | 010110 | 1100 |
| 8 | 111110 | 101100 | 1101 |

Then, the sets test $_{j}$ are as follows:

| $j$ | test $_{j}$ |
| :---: | :---: |
| 2 | $14,15,26,30,32,33,48,52$ |
| 5 |  |
| 6 | $7,24,36,41,54,59$ |
| 7 |  |
| 8 | $34,35,48,49$ |

We see that both test ${ }_{5}$ and test $_{7}$ are empty sets, so this pair is a wrong pair and is discarded by the filtering operation.

Now suppose that we have a pair such that $\mid$ test $t_{j} \mid>0$ for $j=2,5,6,7,8$, so that it survives the filtering operation. (Of course, we do not know if the pair is a right pair or a wrong pair.) We say that the bitstring $J_{2} J_{5} J_{6} J_{7} J_{8}$ of length 30 is suggested by the pair if $J_{j} \in$ test $t_{j}$ for $j=2,5,6,7,8$. The number of suggested bitstrings is

$$
\prod_{j \in\{2,5,6,7,8\}} \mid \text { test } t_{j} \mid .
$$

It is not unusual for the number of suggested bitstrings to be quite large (for example, greater than 80000 ).

Suppose we were to tabulate all the suggested bitstrings obtained from the $N$ pairs that were not discarded by the filtering operation. For every right pair, the correct bitstring $J_{2} J_{5} J_{6} J_{7} J_{8}$ will be a suggested bitstring. This correct bitstring will be counted about $3 N / 16$ times. Incorrect bitstrings should occur much less often, since they will occur essentially at random and there are $2^{30}$ possibilities (a very large number).

It would get extremely unwieldy to tabulate all the suggested bitstrings, so we use an algorithm that requires less space and time. We can encode any test ${ }_{j}$ as a vector $T_{j}$ of length 64, where the $i$ th coordinate of $T_{j}$ is set to 1 (for $0 \leq i \leq 63$ ) if the bitstring of length six that is the binary representation of $i$ is in the set $t e s t_{j}$; and the $i$ th coordinate is set to 0 otherwise (this is essentially the same as the counter array representation that we used in the 3 -round attack).

For each remaining pair, construct these vectors as described above, and name them $T_{j}^{i}, j=2,5,6,7,8,1 \leq i \leq N$. For $I \subseteq\{1, \ldots, N\}$, we say that $I$ is allowable if for each $j \in\{2,5,6,7,8\}$, there is at least one coordinate equal to $|I|$ in the vector

$$
\sum_{i \in I} T_{j}^{i}
$$

If the $i$ th pair is a right pair for every $i \in I$, then the set $I$ is allowable. Hence, we expect there to be an allowable set of size (approximately) $3 N / 16$, which we hope will suggest the correct key bits and no other. It is a simple matter to construct all the allowable sets $I$ by means of a recursive algorithm.

## Example 3.5

We did some computer runs to test this approach. A random sample of 120 pairs of plaintexts with the specified $x$-ors was generated, and these were encrypted using the same (random) key. We present the 120 pairs of ciphertexts and corresponding plaintexts in hexadecimal form in Table 3.1.

When we compute the allowable sets, we obtain $n_{i}$ allowable sets of cardinality $i$, for the following values:

| $i$ | $n_{i}$ |
| ---: | ---: |
| 2 | 111 |
| 3 | 180 |
| 4 | 231 |
| 5 | 255 |
| 6 | 210 |
| 7 | 120 |
| 8 | 45 |
| 9 | 10 |
| 10 | 1 |

The unique allowable set of size 10 is

$$
\{24,29,30,48,50,52,55,83,92,118\}
$$

In fact, it does arise from the 10 right pairs. This allowable set suggests the correct key bits for $J_{2}, J_{5}, J_{6}, J_{7}$ and $J_{8}$ and no others. They are as follows:

$$
\begin{aligned}
& J_{2}=011001 \\
& J_{5}=110000 \\
& J_{6}=001001 \\
& J_{7}=101010
\end{aligned}
$$

FIGURE 3.14
Another 3-round characteristic

| $L_{0}^{\prime}=00200008_{16}$ | $R_{0}^{\prime}=00000400_{16}$ |  |
| :--- | :--- | :--- | :--- |
| $L_{1}^{\prime}=00000400_{16}$ | $R_{1}^{\prime}=00000000_{16}$ | $p=1 / 4$ |
| $L_{2}^{\prime}=00000000_{16}$ | $R_{2}^{\prime}=00000400_{16}$ | $p=1$ |
| $L_{3}^{\prime}=00000400_{16}$ | $R_{3}^{\prime}=00200008_{16}$ | $p=1 / 4$ |

$$
J_{8}=100011
$$

Note that all the allowable sets of cardinality at least 6 , and all but three of the allowable sets of cardinality 5 , arise from right pairs, since $\binom{10}{5}=252$ and $\binom{10}{i}=n_{i}$ for $6 \leq i \leq 10$.

This method yields 30 of the 56 key bits. By means of a different 3-round characteristic, presented in Figure 3.14, it is possible to compute 12 further key bits, namely those in $J_{1}$ and $J_{4}$. Now only 14 key bits remain unknown. Since $2^{14}=16384$ is quite small, an exhaustive search can be used to determine the remaining 14 key bits.

The entire key (in hexadecimal, including parity-check bits) is:
34E9F71A20756231.

As mentioned above, the 120 pairs are given in Table 3.1. In the second column, a * denotes that a pair is a right pair, while a ${ }^{* *}$ denotes that the pair is an identifiable wrong pair and is discarded by the filtering operation. Of the 120 pairs, 73 are identified as being wrong pairs by the filtering process, so 47 pairs remain as "possible" right pairs. ]

### 3.6.3 Other examples of Differential Cryptanalysis

Differential cryptanalysis techniques can be used to attack DES with more than six rounds. An 8 -round DES requires $2^{14}$ chosen plaintexts, and $10-, 12$-, 14 and 16 -round DESs can be broken with $2^{24}, 2^{31}, 2^{39}$ and $2^{47}$ chosen plaintexts, respectively. The attacks on more than 10 rounds are probably not practical at this time.

Several substitution-permutation product ciphers other than DES are also susceptible (to varying degrees) to differential cryptanalysis. These cryptosystems include several substitution-premutation cryptosystems that have been proposed in recent years, such as FEAL, REDOC-II, and LOKI.

### 3.7 Notes and References

A nice article on the history DES is by Smid and Branstad [SB92]. Federal Information Processing Standards (FIPS) publications concerning DES include the following: description of DES [NBS77]; implementing and using DES [NBS81]; modes of operation of DES [NBS80]; and authentication using DES [NBS85].

Some properties of the S-boxes are studied by Brickell, Moore, and Purtill [BMP87].

The DEC DES chip is described in [EB93]. Wiener's key search machine was described at CRYPTO '93 [WI94].

The time-memory trade-off for DES is due to Hellman [HE80]. A more general time-memory trade-off is presented by Fiat and Naor in [FN91].

The technique of differential cryptanalysis was developed by Biham and Shamir [BS91] (see also [BS93A] and their book [BS93], where cryptanalysis of other cryptosystems is also discussed). Our treatment of differential cryptanalysis is based largely on [BS93].

Another new method of cryptanalysis that can be used to attack DES and other similar cryptosystems is the linear cryptanalysis of Matsui [MA94, MA94A].

Descriptions of other substitution-permutation cryptosystems can be found in the following sources: LUCIFER [FE73]; FEAL [M191]; REDOC-II [CW91]; and LOKI [BKPS90].

## Exercises

3.1 Prove that DES decryption can be done by applying the DES encryption algorithm to the plaintext with the key schedule reversed.
3.2 Let $\operatorname{DES}(x, K)$ represent the encryption of plaintext $x$ with key $K$ using the DES cryptosystem. Suppose $y=\operatorname{DES}(x, K)$ and $y^{\prime}=\operatorname{DES}(c(x), c(K))$, where $c(\cdot)$ denotes the bitwise complement of its argument. Prove that $y^{\prime}=c(y)$ (i.e., if we complement the plaintext and the key, then the ciphertext is also complemented). Note that this can be proved using only the "high-level" description of DES - the actual structure of S-boxes and other components of the system are irrelevant.
3.3 One way to strengthen DES is by double encryption: Given two keys, $K_{1}$ and $K_{2}$, define $y=e_{K_{2}}\left(e_{K_{1}}(x)\right)$ (of course, this is just the product of DES with itself). If it happened that the encryption function $e_{K_{2}}$ was the same as the decryption function $d_{K_{1}}$, then $K_{1}$ and $K_{2}$ are said to be dual keys. (This is very undesirable for double encryption, since the resulting ciphertext is identical to the plaintext.) A key is self-dual if it is its own dual key.
(a) Prove that if $C_{0}$ is either all 0 's or all 1 's and $D_{0}$ is either all 0 's or all 1 's, then $K$ is self-dual.
(b) Prove that the following keys (given in hexadecimal notation) are self-dual:

## FEFEFEFEFEFEFEFE <br> 1F1F1F1F0E0E0E0E <br> E0E0EOE0F1F1F1F1

(c) Prove that if $C_{0}=0101 \ldots 01$ or $1010 \ldots 10$ (in binary), then the $x$-or of the bitstrings $C_{i}$ and $C_{17-i}$ is $1111 \ldots 11$, for $1 \leq i \leq 16$ (a similar statement holds for the $D_{i}$ 's).
(d) Prove that the following pairs of keys (given in hexadecimal notation) are dual:

```
E001E001F101F101 01E001E001F101F1
FE1FFE1FFE0EFE0E 1FFE1FFE0EFE0EFE
E01FF01FFF10FF10 1FE01FE00EF10EF1
```

3.4 A message authentication code (MAC) can be produced by using CFB mode, as well as by using CBC mode. Given a sequence of plaintext blocks $x_{1} \ldots x_{n}$, suppose we define the initialization vector IV to be $x_{1}$. Then encrypt $x_{2} \ldots x_{n}$ using key $K$ in CFB mode, obtaining $y_{1} \ldots y_{n-1}$ (note that there are only $n-1$ ciphertext blocks). Finally, define the MAC to be $e_{K}\left(y_{n-1}\right)$. Prove that this MAC is identical to the MAC produced in Scction 3.4.1 using CBC mode.
3.5 Suppose a sequence of plaintext blocks, $x_{1} \ldots x_{n}$, is encrypted using DES, producing ciphertext blocks $y_{1} \ldots y_{n}$. Suppose that one ciphertext block, say $y_{i}$, is transmitted incorrectly (i.e., some l's are changed to 0's and vice versa). Show that the number of plaintext blocks that will be decrypted incorrectly is equal to one if ECB or OFB modes were used for encryption; and equal to two if CBC or CFB modes were used.
3.6 The purpose of this question is to investigate a simplified time-memory trade-off for a chosen plaintext attack. Suppose we have a cryptosystem in which $\mathcal{P}=\mathcal{C}=\mathcal{K}$, which attains perfect secrecy. Then it must be the case that $e_{K}(x)=e_{K_{1}}(x)$ implies $K=K_{1}$. Denote $\mathcal{P}=Y=\left\{y_{1}, \ldots, y_{N}\right\}$. Let $x$ be a fixed plaintext. Define the function $g: Y \rightarrow Y$ by the rule $g(y)=e_{y}(x)$. Define a directed graph $G$ having vertex set $Y$, in which the edge set consists of all the directed edges of the form $\left(y_{i}, g\left(y_{i}\right)\right), 1 \leq i \leq N$.
(a) Prove that $G$ consists of the union of disjoint directed cycles.
(b) Let $T$ be a desired time parameter. Suppose we have a set of elements $Z=\left\{z_{1}, \ldots, z_{m}\right\} \subseteq Y$ such that, for every element $y_{i} \in Y$, either $y_{i}$ is contained in a cycle of length at most $T$, or there exists an element $z_{j} \neq y_{i}$ such that the distance from $y_{i}$ to $z_{j}$ (in $G$ ) is at most $T$. Prove that there exists such a set $Z$ such that

$$
|Z| \leq \frac{2 N}{T}
$$

so $|Z|$ is $O(N / T)$.
(c) For each $z_{j} \in Z$, define $g^{-T}\left(z_{j}\right)$ to be the element $y_{i}$ such that $g^{T}\left(y_{i}\right)=z_{j}$, where $g^{T}$ is the function that consists of $T$ iterations of $g$. Construct a table $X$ consisting of the ordered pairs $\left(z_{j}, g^{-T}\left(z_{j}\right)\right)$, sorted with respect to their first coordinates.

A pseudo-code description of an algorithm to find $K$, given $y=e_{K}(x)$, is presented in Figure 3.15. Prove that this algorithm finds $K$ in at most $T$ steps. (Hence the time-memory trade-off is $O(N)$.)

FIGURE 3.15
Time-memory trade-off

```
\(y_{s t a r t}=y\)
backup \(=\) false
while \(g(y) \neq y_{\text {start }}\) do
        if \(y=z_{j}\) for some \(j\) and not backup then
        \(y=g^{-T}\left(z_{j}\right)\)
        backup \(=\) true
        else
            \(y=g(y)\)
        \(K=y\)
```

FIGURE 3.16
Differential attack on 4-round DES
Input: $L_{0} R_{0}, L_{0}^{*} R_{0}^{*}, L_{3} R_{3}$ and $L_{3}^{*} R_{3}^{*}$, where $L_{0}^{\prime}=20000000_{16}$ and $R_{0}^{\prime}=$ $00000000_{16}$

1. compute $C^{\prime}=\mathrm{P}^{-1}\left(R_{4}^{\prime}\right)$
2. compute $E=\mathrm{E}\left(L_{4}\right)$ and $E^{*}=\mathrm{E}\left(L_{4}^{*}\right)$
3. for $j=2$ to 8 do
compute test ${ }_{j}\left(E_{j}, E_{j}^{*}, C_{j}^{\prime}\right)$
(d) Describe a pseudo-code algorithm to construct the desired set $Z$ in time $O(N T)$ without using an array of sizc $N$.
3.7 Compute the probabilities of the following 3-round characteristic:

| $L_{0}^{\prime}=00200008_{16}$ | $R_{0}^{\prime}=00000400_{16}$ |  |
| :--- | :--- | :--- | :--- |
| $L_{1}^{\prime}=00000400_{16}$ | $R_{1}^{\prime}=0000000_{16}$ | $p=?$ |
| $L_{2}^{\prime}=00000000_{16}$ | $R_{2}^{\prime}=00000400_{16}$ | $p=?$ |
| $L_{3}^{\prime}=00000400_{16}$ | $R_{3}^{\prime}=00200008_{16}$ | $p=?$ |

3.8 Here is a differential attack on a 4-round DES. It uses the following characteristic, which is a special case of the characteristic presented in Figure 3.10:

| $L_{0}^{\prime}=20000000_{16}$ | $R_{0}^{\prime}=00000000_{16}$ |  |
| :--- | :--- | :--- | :--- |
| $L_{1}^{\prime}=00000000_{16}$ | $R_{1}^{\prime}=20000000_{16}$ | $p=1$ |

(a) Suppose that the following algorithm presented in Figure 3.16 is used to compute sets test $t_{2}, \ldots$ test $t_{8}$. Show that $J_{j} \in$ test $_{j}$ for $2 \leq j \leq 8$.
(b) Given the following plaintext-ciphertext pairs, determine the key bits in $J_{2}, \ldots, J_{8}$.

| plaintext | ciphertext |
| :---: | :---: |
| 18493AC485B8D9A0 | E332151312A18B4F |
| 38493AC485B8D9A0 | 87391C27E5282161 |
| $482765 D D D 7009123$ | B5DDD8339D82D1D1 |
| $682765 D D D 7009123$ | 81F4B92BD94B6FD8 |
| ABCD098733731FF1 | 93A4B42F62EA59E4 |
| 8BCD098733731FF1 | ABA494072BF411E5 |
| 13578642AAFFEDCB | FDEB526275FB9D94 |
| 33578642AAFFEDCB | CC8F72AAE685FDB1 |

(c) Compute the entire key ( 14 key bits remain to be determined, which can be done by exhaustive search).
